18 Naviating the document on a computer

19 There are links throughout the PDF document, identified by dark blue text.
20 Clicking on these will take you to the relevant hypothesis, footnote, citation,
21 figure, table, section, or URL. If you are using Preview (on a Mac) then you can
22 subsequently return back to where you clicked on the link by pressing the key
23 combination $\text{⌘}+\text{[}$ (the command key with the left square bracket). In Adobe
24 Acrobat the key combination is $\text{⌘}+\leftarrow$ (the command key with the left arrow
25 key) for Mac and $\text{Alt}+\leftarrow$ (the Alt key with the left arrow key) for Windows.

26

27

28 Reproducibility

29 This thesis was written using `rmarkdown` (Xie et al., 2018) with `bookdown`
30 (Xie, 2016), using `renv` (Ushey, 2021) to create reproducible environments, and
31 `targets` (Landau, 2021) to create a reproducible pipeline. Typesetting was done
32 with L^AT_EXbased on the `oxforddown` template (Lyngs, 2019). All the components
33 required to reproduce this document can be found at the Github repository https://github.com/shirdekel/phd_thesis.

39 Research Ethics Committee (HREC).

40 Project No.: 2019/056

41 Project Title: Business decision making

Abstract

43 Capital allocation decisions are critical for large organisations. Management
44 research mainly considers such decisions from an organisational perspective, largely
45 overlooking potential psychological influences. Therefore, this thesis investigated
46 cognitive processes that affect capital allocation decisions. Three studies examined
47 how participants integrated multiple kinds of cues when making their decisions. Each
48 study presented participants with both statistical information and non-numerical
49 semantic information. In each study, participants had the opportunity to leverage a
50 statistical concept that arguably should be the sole basis of the decision. The first
51 study showed participants sequential risky choices without intermittent feedback.
52 Participants could have combined the risk across decisions to reduce the overall
53 potential loss. However, they struggled to do this, unless it was depicted visually.
54 The second study asked participants to allocate a budget across a set of business
55 projects. Participants could have used the variance associated with the provided
56 forecast estimates to choose which metrics to use for the allocation. However,
57 they only appropriately used this information when it was expressed verbally, and
58 did not when it was expressed numerically. In the third study, participants saw
59 projects with conflicting statistical and anecdotal evidence. The anecdotes were
60 either similar or dissimilar to the target project. Participants could have clarified
61 the conflicting evidence by using provided information about the distribution from
62 which the anecdote was sampled. However, they ignored this information. Despite
63 this, participants moderated their use of the anecdote by its similarity to the target
64 project. These results show that people's capital allocation decisions are bounded
65 by a limited understanding of certain statistical concepts, but that they are capable
66 of more nuanced choice when properly scaffolded.

List of Figures

200

201	1.1 An example of the value function in prospect theory.	14
202	2.1 The outcome probability distribution of the Samuelson (1963) gamble 203 (50% chance of gaining \$200 and a 50% of losing \$100) played 10 times.	33
204	2.2 Example of a project choice display in Experiment 1. Border added 205 for clarity.	42
206	2.3 The display seen by those in the aware condition of Experiment 1. 207 Border added for clarity.	43
208	2.4 Mean proportions of decisions to invest in each set of 10 projects, by 209 awareness condition. Error bars represent 95% confidence intervals. 210 Raw data are plotted in the background.	45
211	2.5 Mean proportions of decisions to invest in each set of 10 projects, by 212 presentation condition. Error bars represent 95% confidence intervals. 213 Here, however, the intervals are so narrow that they are sometimes 214 obscured by the mean indicators in the plot. Raw data are plotted 215 in the background.	46
216	2.6 Mean proportions of decisions to invest in each set of 10 projects, by 217 similarity and presentation conditions. In mixed factorial designs, 218 error bars cannot be used to make inferences by “eye” across all 219 conditions. Therefore, error bars are not included. Raw data are 220 plotted in the background.	47
221	2.7 Proportion of project acceptance in the separate presentation condition, 222 by trial and awareness conditions. LOESS method was used 223 for smoothing over trials and the shading represents 95% confidence 224 intervals.	48
225	2.8 An example of a display seen by those in the separate distribution- 226 present condition of Experiment 2.	54

List of Figures

227	2.9	Mean proportion of project acceptance for the presentation, awareness, and distribution effects. The condition on the left of each effect is the reference condition (separate presentation, naive awareness, distribution absent). As such, it is identical for the three effects. Error bars represent 95% confidence intervals. Raw data are plotted in the background.	55
233	2.10	Mean project acceptance for separate presentation, distribution absent condition, by awareness and trial. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals.	56
237	4.1	An example of a high alignment display in Experiment 1.	81
238	4.2	An example of a low alignment display in Experiment 1. Border added for clarity.	82
240	4.3	The allocation task. Border added for clarity.	83
241	4.4	Mean allocation across NPV amount, by alignment and reliability amount conditions. In mixed factorial designs, error bars cannot be used to make inferences by “eye” across all conditions. Therefore, error bars are not included. Raw data are plotted in the background. When interpreting this figure, consider the linear trends in NPV amount.	85
247	4.5	An example of a low alignment low reliability display in Experiment 2. Border added for clarity.	88
249	4.6	An example of a high alignment high reliability display in Experiment 2.	89
250	4.7	Mean allocation across NPV amount, by alignment and reliability amount conditions. Error bars represent 95% confidence intervals, calculated from the within-subjects SEs using the method from Cousineau and O’Brien (2014). Raw data are plotted in the background.	91
254	4.8	An example of a low alignment, low verbal reliability display in Experiment 3.	96
256	4.9	An example of a high alignment, high numerical reliability display in Experiment 3.	97
258	4.10	Mean allocation across NPV amount, by alignment, reliability amount, and reliability type conditions. Error bars represent 95% confidence intervals, calculated from the within-subjects SEs using the method from Cousineau and O’Brien (2014). Raw data are plotted in the background.	100
263	6.1	Focal project display for the anecdote only condition in Experiment 1.	120

List of Figures

264	6.2	Focal project display for the statistics only, anecdote & statistics, and anecdote & enhanced statistics conditions in Experiment 1.	121
265	6.3	Anecdote display for those in the high alignment condition in Experiment 1.	123
266	6.4	Anecdote display for those in the low alignment condition in Experiment 1.	124
267	6.5	Mean allocation to the target project for the statistics only condition and the two anecdote & statistics conditions. Error bars represent 95% confidence intervals. Raw data are plotted in the background.	125
268	6.6	Mean allocation to the target project, by similarity and anecdote conditions (excluding the statistics only condition). Error bars represent 95% confidence intervals. Raw data are plotted in the background.	126
269	6.7	Mean allocation to the target project, by specific relevance rating and similarity condition. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals. Raw data are plotted in the background.	127
270	6.8	An example of the anecdote display in the negative valence, low similarity condition of Experiment 2.	133
271	6.9	An example of the focal projects in the negative valence, low similarity condition of Experiment 2.	134
272	6.10	An example of an anecdote display in the positive valence, high similarity condition of Experiment 2.	135
273	6.11	An example of the focal projects in the positive valence, high similarity condition of Experiment 2.	136
274	6.12	Mean allocation to the target project, by similarity and valence conditions. In mixed factorial designs, error bars cannot be used to make inferences by “eye” across all conditions. Therefore, error bars are not included. Raw data are plotted in the background.	137
275	6.13	Mean allocation difference between the statistics only condition and the anecdote & statistics condition, by similarity and valence conditions. The horizontal dashed line shows the point in which the two allocations were equivalent. Values that are higher than this line represent participants that allocated more when seeing only the statistics than when seeing the statistics with an anecdote. Error bars represent 95% confidence intervals, calculated from the within-subjects SEs using the method from Cousineau and O’Brien (2014). Raw data are plotted in the background.	139

List of Figures

302	6.14 Mean allocation to the target project, by specific relevance rating, similarity condition, and valence condition. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals. Raw data are plotted in the background.	140
306	A.1 Experiment 1 instructions. Border added for clarity.	166
307	A.2 The outcome distribution of the 10 gambles used in Experiment 1. Border added for clarity.	167
308	A.3 Proportion of project acceptance by trial, similarity, awareness, and presentation conditions. LOESS is used for smoothing over trials, and the shading represents 95% confidence intervals.	168
309	A.4 Experiment 2 project number question. Border added for clarity. . .	170
310	A.5 Experiment 2 binary portfolio question. Border added for clarity. .	171
311	A.6 Experiment 2 numerical portfolio question. Border added for clarity.	172
312	A.7 Number of projects participants reported seeing, by condition. . .	173
313	A.8 Mean choice of investing in all 10 projects for the presentation, awareness, and distribution effects. Note, the condition on the left of each effect is the reference condition (separate presentation, naive awareness, distribution absent). As such, it is identical for the three effects.	174
314	A.9 Mean number of projects chosen in the follow-up for the presentation, awareness, and distribution effects. Note, the condition on the left of each effect is the reference condition (separate presentation, naive awareness, distribution absent). As such, it is identical for the three effects.	175
315	A.10 Mean project acceptance for the 10 gambles. The format of the labels indicates: (gain probability, gain value; loss probability, loss value).	176
316	A.11 Mean project acceptance for the gambles' expected value, positive probability, and positive outcome.	176
317	A.12 An example of a project display in Experiment 3. Border added for clarity.	177
318	A.13 Experiment 3 project expectation question. Border added for clarity.	177
319	A.14 Mean project acceptance for the similarity effect.	178
320	A.15 Mean proportion of project acceptance for the similarity effect. . .	179
321	A.16 Mean project acceptance by similarity and trial.	179
322	A.17 Number of projects participants expected to see, by similarity. . .	180
323	A.18 Number of projects participants reported seeing, by similarity. . .	181

List of Figures

338	A.19 Mean choice of investing in all 10 projects for the similarity effect.	181
339	A.20 Mean number of projects chosen in the follow-up for the similarity effect.	182
340	A.21 Mean project acceptance for the 10 gambles. The format of the labels indicate: (gain probability, gain value; loss probability, loss value).	183
341	A.22 Mean project acceptance for the gambles' expected value, positive probability, and positive outcome.	183
342	A.23 Instructions for those in the naive condition of Experiment 4. Border added for clarity.	185
343	A.24 Instructions for those in the aware condition of Experiment 4. Border added for clarity.	186
344	A.25 An example of a project display in Experiment 4. Border added for clarity.	186
345	A.26 Mean project acceptance for the awareness effect.	187
346	A.27 Mean proportion of project acceptance for the awareness effect.	188
347	A.28 Mean project acceptance by awareness and trial.	189
348	A.29 Number of projects participants expected to see, by awareness.	190
349	A.30 Number of projects participants reported seeing, by awareness.	190
350	A.31 Mean choice of investing in all 20 projects for the awareness effect.	191
351	A.32 Mean number of projects chosen in the follow-up for the awareness effect.	191
352	A.33 Mean project acceptance for the 20 gambles. The format of the labels indicate: (gain probability, gain value; loss probability, loss value).	192
353	A.34 Mean project acceptance for the gambles' expected value, positive probability, and positive outcome.	193

506

507 Much of modern life depends on large organisations. General Electric (GE)
508 makes the engines that power our aircrafts, Johnson & Johnson makes our shampoo,
509 and Google allows us to search the internet. The areas of our lives that are less
510 affected by such private firms depend on public sector organisations such as public
511 hospitals, schools, and police. The justification for the existence of organisations
512 of this size is that the particular combination of individual divisions, alongside a
513 corporate management, will lead to better performance for each of the divisions
514 than they would have been able to generate individually. In other words, the
515 assumption is that such organisations create a synergy—the quality of the whole
516 will be greater than the sum of its parts.

517 Multi-divisional organisations are typically organised in a hierarchical structure,

1. Introduction

518 with a corporate management team and subsidiary divisions. Each division can
519 be made up of several business units. For instance, some of GE's divisions include
520 GE Aviation and GE Healthcare. Similarly, in the public sector, a hospital system
521 may operate through multiple individual hospitals in different regions.

522 Such organisations therefore need to make capital allocation decisions. That is,
523 given a limited amount of financial resources, how best to invest in the multiple
524 divisions? Equally? Pick a winner? What metric should be used to compare
525 across divisions? Capital allocation is a critical process to the operation and
526 development of multi-divisional organisations.

527 The products and services that arise from organisations are necessarily a result
528 of the work of many people. In GE, for instance, the factories that generate aircraft
529 engines need to be staffed by production line workers, accountants are needed
530 for bookkeeping, and software engineers are needed to design and maintain the
531 production systems. Despite this, many important strategic decisions ultimately
532 come from a very small number of people. The decisions that the CEO or other
533 lower level executives make can have large consequences on the life of the company.

534 It is often assumed that a few people having a lot of decision-making power is
535 for the best. Managers of large organisations often appear to be bold and effective
536 decision-makers. It appears that their position of power and wealth was necessarily
537 arrived at through high competence and rational decision-making, suggesting that
538 the organisation is in good hands. However, there are three reasons why it may be
539 concerning that much of an organisation's future—and by extension often many
540 more components of the economy—depends on the decisions of a few individuals.
541 First, the role of survivorship bias in obtaining the manager's role is unclear, because
542 the number of managers that used the same management strategy and failed is
543 unknown. Second, decades of work have shown that people's decision-making is
544 often fallible and that job experience does not always alleviate this fallibility. Third,
545 managers of large organisations often face uncertain environments, which increases
546 the likelihood of managers facing psychological biases.

1. Introduction

547 There are many examples of companies that suffered due to such biases. Over-
548 confidence and confirmation bias likely played a part in Blockbuster's famous refusal
549 of an offer to buy Netflix in 2000 (Meissner et al., 2015). Roxburgh (2003) identified
550 how Equitable Life Assurance Society unnecessarily anchored on previous interest
551 rate performance and was unprepared when rates changed. In an example of the
552 sunk-cost fallacy, the London Stock Exchange continued investing in an automated-
553 settlement system even when it no longer remained profitable. The Bank of England
554 needed to step in and stop the project. Overconfidence in market entry is also
555 a common issue, illustrated by EMI's introduction into the medical-diagnostics
556 market with the CT scanner (Camerer & Lovallo, 1999; Horn et al., 2005). By
557 underestimating the competition and overestimating their own capabilities they
558 eventually incurred losses and exited the market.

559 One class of biases has not been well studied: capital allocation biases. While
560 some previous work investigating these biases exists (e.g., Bardolet et al., 2011),
561 many questions still remain unanswered. This is a rather large hole in the literature
562 because capital allocation decisions are at the centre of executive and lower level
563 managers' roles. When making capital allocation decisions, there are elements of
564 the decision-making environment that can be deceiving for managers. This thesis
565 examines how the framing of a series of business projects affects people's decisions
566 about those projects. Specifically, the same set of projects, presented in aggregate
567 form, is much more likely to be accepted. Further, sometimes people are distracted
568 by extraneous semantic information, such as the relative similarity of the options.

569 The results of the thesis show that although people in general make sensible
570 decisions, they fail to moderate them appropriately when presented with critical
571 information. Specifically, information about metric variance is ignored even when
572 other metrics are available. Further, people seem to appropriately use statistical
573 and anecdotal information based on relevance to the situation at hand, but ignore
574 information about the sampling of the anecdote. Not appropriately using these
575 kinds of statistical concepts has important financial consequences, discussed below.

1. Introduction

576 All the experiments in the thesis use laypeople, except for one experiment.
577 However, past work generally shows the same biases in managers and laypeople (with
578 some showing more bias in managers, e.g., Haigh & List, 2005). Further, upcoming
579 studies will directly test managers to determine any potential expertise effects.

580 Section 1.1 will explain how the capital allocation process functions in hierarchical
581 organisations and why it is necessary to analyse such a process with a psychological
582 approach. Section 1.2 reviews the literature on decision-making biases and how
583 these may apply to capital allocation decisions. Section 1.3 will then summarise
584 the rest of the thesis chapters.

585 1.1 Capital allocation in hierarchical organisa- 586 tions

587 The purpose of a multi-divisional organisation is to generate more value than
588 any of the individual divisions combined. The whole should be greater than the
589 sum of its parts. Previous work suggests that this is achieved due to factors such
590 as reduced transaction costs (Coase, 1937; Liebeskind, 2000; Teece, 1980, 1982;
591 Williamson, 1981), shared resources (Barney, 1991; Wernerfelt, 1984), increased
592 competitive advantage (Porter, 1980, 1985), increased monitoring (Gertner et al.,
593 1994), and increased synergies (Barney, 1988). The underlying logic is the same:
594 a multi-divisional organisation will be successful if it manages its divisions using
595 processes and resources that are shared or, better yet, are complementary.

596 In order to successfully manage multiple units, large organisations developed a
597 hierarchical structure. Bower (1970) identified three levels of the typical management
598 hierarchy: business, division, and corporate. These are equivalent to front-line (or
599 bottom), middle, and top level managers (Noda & Bower, 1996). Early theorists
600 suggested that the strategy for the organisation's growth is driven completely by the
601 top managers; the rest of the organisation simply enacts their proposals. However,
602 Mintzberg and Waters (1985) emphasised the role of an emergent strategy, in
603 which lower level managers affect change in the organisation's strategy. Other

1. Introduction

604 work proposed and found evidence for an iterated process in which a strategic
605 context may be set by top managers, but business projects advanced by lower
606 level managers also contribute to driving the strategy of the organisation (Bower,
607 1970; Burgelman, 1983; Noda & Bower, 1996).

608 The way that capital is allocated in an organisation is very important to its
609 growth and longevity. This process is a part of the broader process of resource
610 allocation. A *resource* can refer to many types of assets that an organisation owns,
611 both tangible and intangible, of which capital is only one (Wernerfelt, 1984). The
612 capital allocation process itself is an important driver of the strategic outcomes
613 of an organisation (Bower, 1970; Bower & Gilbert, 2005), and as a result, is an
614 important influence on its financial performance (e.g., Arrfelt et al., 2015; Bardolet
615 et al., 2010). Sengul et al. (2019, p. 72) describe intra-firm capital allocation as “(i)
616 a process of determination, comparison, and selection among multiple investment
617 alternatives, (ii) taking place across organizational levels of the firm, and (iii)
618 influenced and constrained by the external context in which the firm is situated.”
619 In capital allocation, business-level managers typically formulate project proposals,
620 which their division managers then evaluate. The division managers then choose
621 the projects to send for final approval with the corporate managers. The supply of
622 available capital is also influenced by external sources such as investors, competitors,
623 and customers. However, this thesis focuses on the comparison and selection
624 processes that are relevant during business project evaluation.

625 Managers ultimately have only limited information about the projects that
626 they evaluate. They typically have access to descriptive information about the
627 investment and its known properties, but also are provided with financial metrics
628 that estimate the returns on the investment. There are many such metrics; they
629 usually attempt to encapsulate a trade-off between predicted future gains, present
630 losses (in the form of the capital spent to pay for the investment), and opportunity
631 costs. Examples include Net Present Value (NPV), Internal Rate of Return (IRR),
632 Return on Investment (ROI), Cost-Benefit (CB), and Pay-Back Period (PBP).
633 This thesis focuses on NPV, since it is one of the most frequently used metrics for

1. Introduction

project evaluation (Graham & Harvey, 2001; Graham et al., 2015; Remer et al., 1993). NPV is the difference between the money that a project is forecasted to make and the initial investment in its development (accounting for the time value of money), as seen in Equation (1.1):

$$\text{NPV} = \sum_{t=0}^n \frac{R_t}{(1+i)^t}, \quad (1.1)$$

where t is the time of the cash flow, i is the discount rate, R_t is the net cash flow, and n is the total number of periods. NPV is a useful metric because simply knowing that it is positive suggests that the project that it describes should be profitable. Therefore, metrics such as these have a strong influence on the decision of the manager evaluating a project.

However, there are other influences on project evaluations other than the value of the financial metrics. For instance, politics within or outside the company can lead to situations in which a decision is based on social influence or even manipulation (Garbuio & Lovallo, 2017). Such influence is not necessarily negative; it may involve qualitative feedback from, for instance, a more senior manager (Thamhain, 2014). Research has also shown that the media can have a tangible influence on managerial decision-making (Bednar et al., 2013; B. Liu & McConnell, 2013). Other sources of influence are the organisational structures and incentives that are in place both externally (Kokkinis, 2019) and internally to the organisation (Rajan et al., 2000; Ullrich & Tuttle, 2004). Such dynamics have also been the subject of economic modelling investigations (Cavagnac, 2005; Ortner et al., 2017; Reichelstein, 1997). Project proposals might also be affected by certain approval structures. For instance, managers might submit overly-optimistic project proposals if they know that the corporate team only accepts projects with a certain minimum NPV forecast.

Another potential organisational influence on capital allocation is the extent of diversification present in an organisation. A diversified organisation is one that possesses different divisions that are unrelated in some way. Penrose (1959/2009, p. 96) defined it as such:

1. Introduction

661 a firm diversifies its productive activities whenever, without entirely
662 abandoning its old lines of product, it embarks upon the production of
663 new products, including intermediate products, which are sufficiently
664 different from the other products it produces to imply some significant
665 difference in the firm's production or distribution programmes.

666 Previous work found that organisations that are made up of more related divisions
667 are more successful than those that are made up of unrelated divisions (Harrison et
668 al., 1993; Rumelt, 1974; Shelton, 1988; Wernerfelt & Montgomery, 1988). This is also
669 true within business divisions (P. S. Davis et al., 1992). However, *more* diversified
670 firms have also been shown to be associated with profitability (Grant & Jammie,
671 1988). This is usually explained by the ability for such firms to avoid risk associated
672 with any one market. Some of the discrepancy in diversification findings has been
673 explained to be due to the specific measures used (Lubatkin & Shrieves, 1986). It
674 may also be because most studies used Standard Industrial Classification (SIC)
675 codes to measure diversification (e.g., Rumelt, 1974), whereas others operationalised
676 it using other approaches (e.g., resource-based; Harrison et al., 1993).

677 The advantage that related organisations have had has been explained through
678 *synergies* (Barney, 1988). That is, an organisation with two divisions that can use
679 their resources to better one another are better off together than separately. The
680 1960s saw a general rise in mergers and acquisitions from executives seeking to
681 diversify their organisations. However, doing so simply for the sake of increasing
682 divisions, rather than an understanding of the possible synergies, leads to the
683 organisation actually being worth less than the sum of its parts (known as a
684 *diversification discount*; Lang & Stulz, 1994). In fact, many organisations that
685 acquired other businesses to diversify subsequently end up divesting them (Porter,
686 1987). For instance, in 2018 Australian conglomerate Wesfarmers demerged its
687 Coles division, a successful retailer. Since then, the share price for both companies
688 has risen by approximately 62% and 32%, respectively (Boyd, 2021).

689 While much of the performance of an organisation depends on influences that
690 are external to the individual managers (e.g., organisational, political), psycho-
691 logical factors are often also quite consequential. For instance, on the one hand,

1. Introduction

organisational factors such as relevant support teams and approval processes may influence capital allocation depending on the extent of an organisation's extent of diversification. On the other hand, psychological factors such as ability of managers to compare between business project proposals may also impact allocation differently depending on the organisation's diversification. It is likely to be more difficult for a manager to evaluate project proposals from two dissimilar divisions than it is to evaluate those from two similar divisions. The organisational influences discussed above often assume that the manager that is making the decisions acts rationally, as per traditional economic theory. However, surveys of executives show that CEOs and CFOs often rely on non-financial factors for capital allocation decisions (Graham et al., 2015). Executives in these surveys identified manager reputation and confidence as two of the most important factors for capital allocation decisions. Further, research in psychology has shown that cognitive biases can influence such capital allocation decisions. Section 1.2 discusses such biases and the relevant implications for the thesis.

1.2 The psychology of capital allocation

Managers of large organisations are generally assumed to have a superior decision-making capability to non-managers. However, managerial decision-making involves many of the same processes that have been shown to be affected by psychological biases in the general population (Das & Teng, 1999; McCray et al., 2002; Schwenk, 1984). Further, an organisation's success ultimately depends on strategic decisions made by top level managers (Mazzolini, 1981). Therefore, despite early work attempting to analyse such decisions using a structured organisational analysis (e.g., Mintzberg et al., 1976), it is important to understand the potential influence of psychological biases on managerial decisions. Research in the field of behavioural strategy has started to do this (Powell et al., 2011).

Psychological research has shown that people tend to make decisions that are inconsistent with neoclassical economic theory. For instance, Expected Utility

1. Introduction

Theory (EUT; Friedman & Savage, 1948; von Neumann et al., 1944) assumed that people have complete information when making decisions. However, both laypeople and managers of organisations are limited in the amount of information that they have and their ability to use it (Cyert et al., 1956; Simon, 1955). Such inconsistencies with economic prescription are likely to have evolutionary origins, so are sure to be adaptive in certain environments (Bettis, 2017; Gigerenzer, 2008; Haselton et al., 2009). However, there are many situations in which such inconsistency with economic theory can have bad consequences.

Research has shown many ways in which the allocation of capital in an organisation can be influenced by psychological biases. For instance, Benartzi and Thaler (2001) found that people tend to allocate their retirement fund equally between the available options, regardless of their composition. This *naive diversification* bias was also found in capital allocation for hierarchical firms (Bardolet et al., 2011). Managers allocated capital equally across the available divisions in the firm, regardless of performance. Analysis of real companies found that this behaviour is damaging to firm performance because it means that lower performing business units get subsidised by higher performing units, which are not operating at their full potential (Arrfelt et al., 2015; Bardolet et al., 2010). Subsequent studies found that business unit size also matters; capital allocation to both the smallest and largest units is disproportionate to their actual profitability levels (Bardolet et al., 2017). This was attributed to a combination of naive diversification and political power effects.

Relatedly, people tend to continue expending capital into investments that appear to be failing (Staw, 1981). This *escalating commitment* is another way that psychological biases can influence allocation in an organisation. This pattern of decision-making is likely a consequence of the sunk cost fallacy, in which people avoid “cutting their losses” even when they know that they cannot recuperate an investment (Parayre, 1995).

Managers also do not always seem to seek profit maximisation. Shapira and Shaver (2014) offered managers and MBA students two investment from

1. Introduction

750 a hypothetical firm: one with the same expected returns as the average of the firm's
751 current investments and one with lower returns than the firm's average returns.
752 However, both investments were profitable, so to maximise firm profits both should
753 be chosen. Instead, participants were more likely to only choose the first investment.
754 It seems that the firm's average returns served as an anchor, so participants did
755 not want to reduce the firm's average returns, regardless of profitability.

756 The way that information is presented can also influence allocations. For
757 instance, Yates et al. (1978) showed that people's evaluations are sensitive to
758 the level of detail in the information provided. They found that people devalued
759 descriptions of university courses more when they had less detail. This may be
760 relevant for managers evaluating project proposals. A proposal might appear more
761 attractive simply due to the level of detail in it, even if the level of detail does
762 not correspond with the quality of each proposal.

763 Further, people tend to be over-confident in their decisions and forecasts. This
764 has been shown in laypeople (E. J. Langer, 1975; Mannes & Moore, 2013; Puri &
765 Robinson, 2007; Soll & Klayman, 2004), as well as in IT professionals (McKenzie
766 et al., 2008) and managers (Barone-Adesi et al., 2013; Kahneman & Lovallo, 1993;
767 Lovallo & Kahneman, 2003). This is important for higher-level managers that
768 evaluate project proposals because the metrics that rely on forecast estimates
769 may be biased by the over-confidence of the lower-level manager that created
770 the proposal. Further, the higher-level manager evaluating the proposal may in
771 turn be over-confident about its prospects due to factors that are unrelated to
772 the underlying value. Overconfidence is also seen when considering the success of
773 projects in hindsight (Bukszar & Connolly, 1988; Christensen-Szalanski & Willham,
774 1991). This means that it less likely that managers will be able to effectively
775 learn from both past mistakes and successes due to the potentially erroneous belief
776 that the outcome was anticipated.

777 Managers often create sensitivity analyses, estimating the worst case, best case,
778 and most likely scenario for a forecast. However, these are likely to be anchored
779 on past experiences that further the manager's existing beliefs. In fact, prior

1. Introduction

research has shown that people are poor at constructing subjective probability distributions (e.g., Alpert & Raiffa, 1982; Schaefer & Borcherding, 1973; Tversky & Kahneman, 1974; von Holstein, 1971). Therefore, this suggests that even if the lower-level managers that construct project proposals calibrate their forecasts so that they are not over-confident, they are still likely to provide inaccurate estimates of their degree of confidence.

The above summarises many of the currently known psychological biases related to capital allocation. This thesis focuses on three essential processes within the capital allocation process: 1. risky choice, 2. the comparison between diversified businesses, and 3. the influence of prior experience. Each of these is prone to separate biases, that are also interrelated. The subsequent subsections review the literature for these processes.

1.2.1 Risky choice

Neoclassical theories such as EUT suggest that when faced with multiple risky options people should choose the option with the highest Expected Value (EV), all else being equal. This means multiplying the value of each option by its probability and comparing the resulting values (first documented in Pascal, 1670/1999). For instance, imagine being presented with the following two choices:

- A) a gamble that involves a 50% chance gaining \$200 and a 50% chance of losing \$100; or
- B) gaining/losing nothing.

In option A, the EV is calculated as $200 \cdot 0.5 - 100 \cdot 0.5 = 50$. Since the EV for option A (50) is higher than the EV for option B (0), EUT would suggest that option A should be chosen.

This basic principle was extended by Bernoulli (1738/1954), who suggested that a persons' subjective value of money differs depending on their current wealth. This *diminishing marginal utility* suggests that the more money a person already has,

1. Introduction

the less value acquiring more money will have for him. For example, the experience of a rich man that finds \$10 on the street is very different to the experience of a homeless man that finds \$10 (Bradley, 2013). Even though \$10 was gained in both cases, \$10 has less value to a person that already has, for example, \$1000, than for a person that initially only has \$10. This principle is usually modelled as an power function (with a fractional exponent).

Prospect theory (Kahneman & Tversky, 1979; Tversky & Kahneman, 1992) challenged EUT by suggesting that people's subjective value of money does not depend on their state of wealth—it depends on a change of wealth from a reference point. This is important because people's subjective value of money is different depending if they are gaining or losing money. Specifically, losses have a stronger psychological impact than equivalent gains. This disparity is one of the most settled and consistent findings in psychology and economics, having been well-replicated (e.g, Ruggeri et al., 2020). The fact that losses loom more than equivalent gains for the vast majority of people is referred to as *loss aversion* (Kahneman & Tversky, 1979). This finding was the primary reason that Daniel Kahneman won the Nobel Prize in Economics in 2002 (Kahneman, 2003). Loss aversion has been found with small amounts of money in experimental settings (Kahneman & Tversky, 1979; Tversky & Kahneman, 1992) and with millions of dollars in corporate settings (Koller et al., 2012; Swalm, 1966). The effect has been found in young children (Harbaugh et al., 2001), the numerous disparate cultures in which it has been tested (Weber & Hsee, 1998), and even in capuchin monkeys (Chen et al., 2006). Furthermore, a neural basis for loss aversion was identified (Tom et al., 2007). Therefore, loss aversion is clearly central to human cognition and behaviour.

The function that represents the value of a prospect describes both loss aversion and diminishing marginal utility, as seen in Equation (1.2):

$$v(x) = \begin{cases} x^\alpha & \text{if } x \geq 0 \\ -\lambda(-x)^\beta & \text{if } x < 0, \end{cases} \quad (1.2)$$

where x is the possible outcome, λ represents the loss aversion coefficient, and α and β represent the diminishing marginal utility for gains and losses, respectively.

1. Introduction

In other words, loss aversion means that losses have more impact than equivalent gains. In fact, the impact of loss aversion can be expressed even more precisely, as a measurement of the ratio of the slopes of the curve for gains and losses. This measure tells us the average amount that losses have more impact than equivalent gains. In a sequel to the original prospect theory paper, Tversky and Kahneman (1992) measured a median coefficient (λ) of 2.25 of loss aversion. This means that people respond to losses 2.25 times more than equivalent gains. Similarly, this paper measured a median exponent (representing diminishing marginal utility, α and β) of 0.88 for both gains and losses. This means that people discount money the more of it they have by a rate of $x^{0.88}$.

Figure 1.1 shows loss aversion as the function being steeper in the domain of losses than the domain of gains. It shows diminishing marginal utility by the slight curve of the function. Equivalent changes in actual wealth from the references point (x-axis) have different impacts on the changes' subjective value (y-axis). An increase in wealth ($x = 1$) brings about an equivalent increase of value ($y = 1^{0.88} = 1$). However, a decrease in the same amount of wealth ($x = -1$) brings about a decrease in value 2.25 times the value of the equivalent gain ($y = -2.25 \cdot (-(-1))^{0.88} = -2.25$).

This research is relevant to capital allocation because the project proposals that managers evaluate invariably involve an element of risk. Therefore, managers are likely to be affected by similar effects on risk that have been shown in laypeople. However, hierarchical organisations offer an even more complex situation. Lovallo et al. (2020) found that the risk profiles of lower-level managers are lower than those of the top managers. They suggest that this may be due to lower-level managers' loss aversion to accepting projects that may jeopardise their job. However, the top managers recognise that a loss in one or more business units is likely to be offset by gains in other units. Such an inconsistency in risk profiles across the levels of an hierarchical organisation fails to take advantage of the benefits of risk aggregation, which has long been understood in external markets (Markowitz, 1952).

Lovallo et al. (2020) suggested that lower-level managers' failure to aggregate risk to the degree desired by top executives is costing companies approximately a

1. Introduction

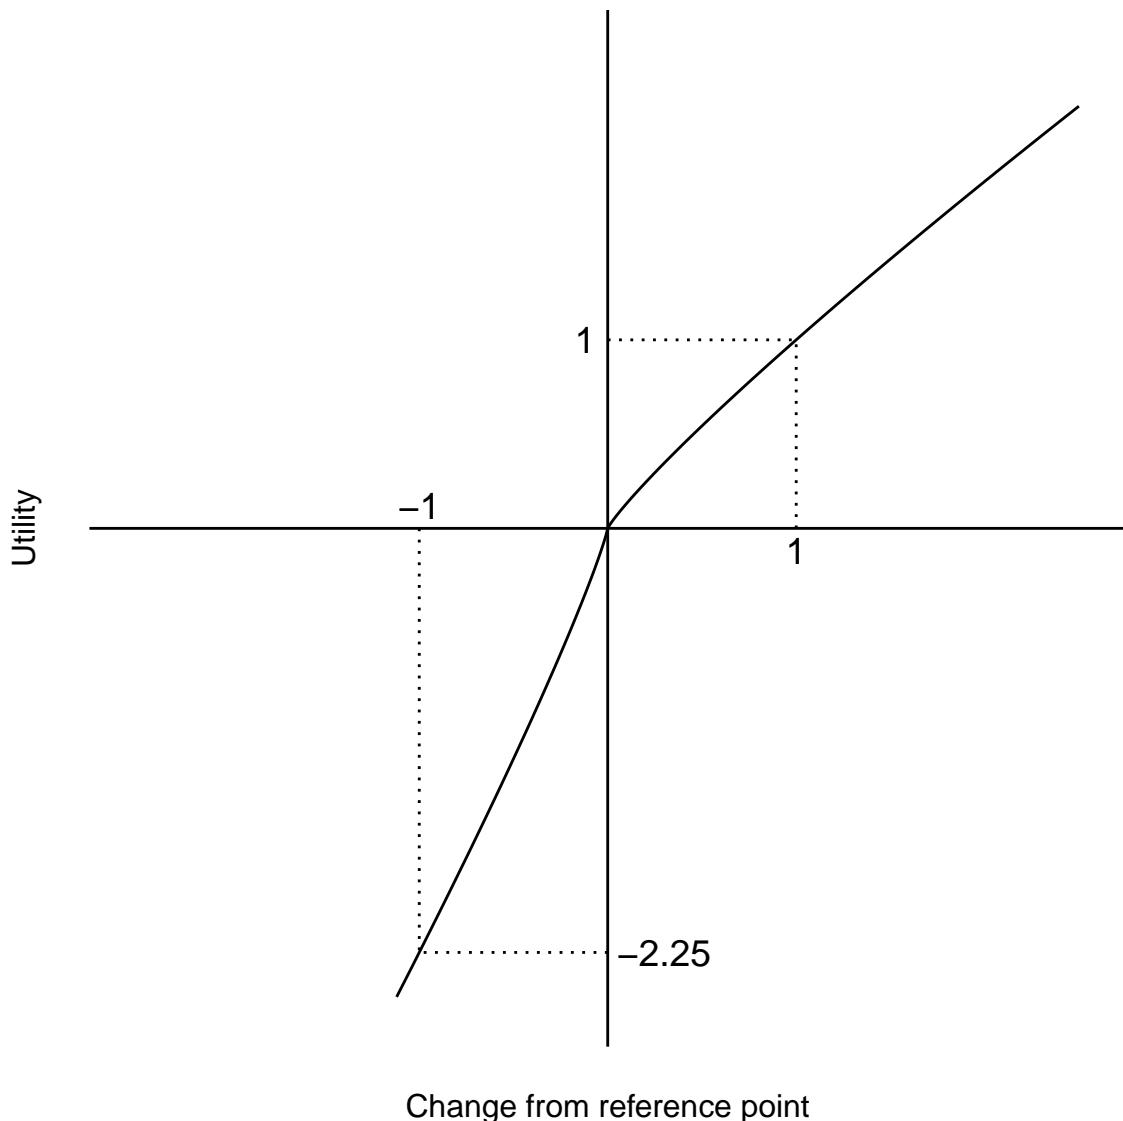

Figure 1.1: An example of the value function in prospect theory.

third of the total EV of new project proposals. This is an example of a negative consequence associated with ignoring statistical concepts such as risk aggregation. It is thus critical to identify ways to support risk aggregation across organisational hierarchies. The psychological literature shows that people's risk aggregation is facilitated through various choice bracketing manipulations. However, there has been no work that investigated such situations without providing participants with feedback in between decisions; this critically limits the external validity of this work because in the real world, organisations evaluate several projects before seeing the outcomes of any one decision. The experiments presented in Chapter 2 investigate

1. Introduction

874 the effects of choice bracketing on risk aggregation without feedback.

875 1.2.2 Project similarity

876 When evaluating project proposals, managers are likely to be influenced by
877 the relative similarity of the available options to each other. The extent to which
878 this may be true is important especially since the increase firm diversification.
879 Organisations are not only varied by the number of divisions which they possess,
880 but also by the extent of diversification. This means that managers are likely to
881 find themselves comparing across dissimilar types of projects.

882 As mentioned above, there are likely many organisational and financial reasons
883 why the extent of diversification in an organisation would impact its performance.
884 However, the impact of psychological factors has not been investigated. Specifically,
885 project similarity, which is an organisational factor, is likely to affect the project
886 comparison process, which is a psychological factor. This may then have downstream
887 consequences on firm performance through, for instance, the kinds of financial metrics
888 that are used and how they are evaluated. Having more similar projects to compare
889 may mean more attributes on which to evaluate, whereas a dissimilar comparison may
890 lead to a situation in which a manager has to rely on potentially unreliable metrics.

891 Structure-mapping theory (SMT; Gentner, 1983; Gentner & Markman, 1997)
892 provides a model of comparison that psychologically distinguishes similar and
893 dissimilar allocation tasks. SMT models comparison as a process of bringing
894 conceptual structures into alignment which, when possible, puts shared dimensions
895 into correspondence. Alignment both highlights when two conceptual structures
896 share dimensions, but also highlights how the two structures differ along those
897 shared dimensions, called *alignable differences*. For example, when comparing two
898 oil discovery projects, all the relevant processes of planning an exploration and
899 measuring the amount of hydrocarbons in a prospect might be identical, but the
900 specific amount measured will be different. This is the alignable difference: a
901 difference between the two projects that is constrained within the same conceptual
902 structure. However, when comparing between an oil field and a refinery, there will be

1. Introduction

significantly more *non-alignable differences*, because the two domains do not share component dimensions. That is, many of the processes that exist in the exploration business unit have a significantly different dimensional structure to those in the refinery business unit, such that it will be difficult to find meaningful alignments. More non-alignable differences mean that there are less opportunities to make meaningful comparisons, and so would make predicting relative project success and ranking their priority more difficult. Chapter 4 experimentally examines business project comparisons and how project alignment affects capital allocation decisions.

When evaluating projects, managers make use of financial metrics, such as NPV. However, such metrics are reliant on forecast estimates of, for instance, future cash flows. Do managers take into account such inherent variance in their decisions? This is especially important to investigate given the above discussion. In cases of non-alignable comparison managers may rely on a potentially unreliable metric. On the other hand, in an alignable comparison, managers might have the option to moderate their choice based on the relative reliability of different metrics. It is important to remember that all such decisions are often very consequential for the manager. That is, the project could ultimately make the company money and lead to future opportunities for the manager, or potentially cause financial harm to the company (and subsequently lead to a job loss). This is another example of the way in which ignoring certain statistical concepts—here metric variance—can have negative consequences for an organisation.

Psychological research shows that laypeople are in general quite poor at using numerical variance information (Batteux et al., 2020; Galesic & Garcia-Retamero, 2010; Konold et al., 1993; Vivaldi & Coville, 2021). However, it is unclear to what extent managers would be sensitive to variance information in the metrics associated with the projects that they evaluate. On the one hand, perhaps managers' financial training will allow a consideration of such variance estimates, but this might not manifest in a situation in which managers have already been shown to be prone to biases. Chapter 4 investigates whether people are as sensitive to verbally-instructed reliability information as they are to numerical reliability information.

1. Introduction

1.2.3 Reasoning from past cases

Managers often use past events to reason and make predictions about the future (Einhorn & Hogarth, 1987). Such past events may be those that happened to the individual manager, a case from the organisation's history, or from an external source. This will especially be the case in a project evaluation scenario when a given project is hard to compare with the other projects at hand. However, managers evaluating project proposals may make inappropriate comparisons when considering the target project to other cases. For instance, when comparing a target problem to other cases, people tend to limit the size of the comparison set to a small number. This is often only a handful of cases, or even one. Doing this might mean only considering potentially irrelevant surface similarity to the current situation and not aligning the underlying causal structure. Further, this might mean not considering other similar projects.

Tversky and Kahneman (1974) discussed a number of biases that may influence such processes. The availability bias is seen when people mistake the ease of retrieval of information for its frequency. Further, research on analogical retrieval showed that people are more likely to retrieve surface similar cases than those with a relational connection (Gentner et al., 1993). As such, managers are likely to recall cases that may not be sufficiently relevant to their target situation and be overly-confident about the frequency of such cases occurring. Such a focus on a particular case might then also lead to an anchoring effect, wherein other decisions might be disproportionately seen as relevant. Tversky and Kahneman (1974) also found that people are not sensitive to properties of sample size such as the greater amount of non-representative outcomes in small samples. This means that managers are even less likely to appreciate the importance of considering a large sample of cases when drawing conclusions to a target problem. Tversky and Kahneman (1974) also note an insensitivity to predictability, in which people do not take into account the reliability of the information that they have to make a prediction. This might mean that managers may struggle to ideally weigh evidence of varying degrees of reliability.

1. Introduction

External sources that might be used to compare to a target situation include business case studies. Considering such examples of prior business decisions or events are the way that most MBAs learn about the business world. Publications such as Forbes or Harvard Business Review publicise various businesses' successes and failures and so may create an allure to use such case studies in the decision-making process. On the other hand, managers may have access to more aggregated data about their industry from, for instance, consultancy companies. How do managers use these various types of evidence in their decision-making?

Research on this topic suggests that managers tend to prefer anecdotes over statistics, unless aided (Wainberg, 2018). This is a concern because Gavetti et al. (2005) suggests that managers often make use of case studies quite poorly. The analogy literature draws a distinction between surface similarity, in which a mapping is made between easily identifiable but potentially functionally irrelevant attributes, and relational similarity, in which the underlying mechanism is considered. Are managers sensitive to the deeper causal mechanisms that underlie the anecdotes they judge? Or are they simply influenced by surface similarity? Chapter 6 investigates the extent to which people moderate their reliance on anecdotes or aggregated data by the relevance of the anecdote to the target project during capital allocation. It also considers whether people are sensitive to information about the distribution from which the anecdote was sampled. Ignoring this statistical concept can have negative consequences for an organisation by potentially over- or under-estimating the relevance of a past case and therefore making an ill-informed investment.

1.3 Chapter overview

In sum, the potential consequences of a diversified hierarchical structure are that business projects will be considered one at a time, and if they are considered together, disparate project types will make comparisons hard. Considering projects one by one might mean that risk is not aggregated across projects and therefore value is lost. The difficulty to compare will lead to both potentially relying on

1. Introduction

unreliable metrics, and relying on improper anecdotal evidence. The thesis is that people often go half-way. They do not completely disregard the normative strategy, but also struggle to moderate their decisions when it comes to statistical concepts such as aggregation, variance, and sampling.

The previous section identified three capital allocation processes that are currently under-studied and so are important to investigate further. First, the evaluation of individual project proposals might lead to managers only considering such projects one at a time, despite the opportunity of aggregating a portfolio of such projects. The choice bracketing literature suggests that there are ways of facilitating such aggregation, but does not investigate this without providing participants inter-trial feedback. Second, in situations in which managers compare multiple projects, the structural alignment literature suggests that managers in diversified firms will struggle to allocate capital, more than those in more integrated firms. Further, these managers might not be sensitive to the variance inherent in the financial metrics they rely on. Third, a difficulty to compare across existing projects might instead mean a reliance on prior case studies from personal or external experience. Research on anecdotal bias suggests that managers might rely more on such case studies than on aggregated data, but it is unclear whether they will use anecdote relevance to moderate their decisions. Further, it is unclear if they will appropriately use information about the anecdote's sample distribution.

The rest of this thesis investigates the psychology of capital allocation decisions in three chapters that describe empirical work, two theoretical chapters, and a general discussion chapter. Chapter 2 describes two experiments that investigate the effects of choice bracketing on risk aggregation without feedback. Chapter 3 is a short theoretical chapter that discusses the difference between evaluating project proposals with inherent budget estimates and the process of allocating an existing budget top-down. Chapter 4 describes three experiments that investigate the effects of alignment and reliability type—verbal or numerical—on allocations. Chapter 5 is another short theoretical chapter that discusses the trade-offs that people make when using information to evaluate project proposal options. Chapter 6 describes

1. Introduction

1020 two experiments that investigate the effects of anecdote similarity on the anecdotal
1021 bias. Finally, Chapter 7 discusses the theoretical and practical implications of
1022 the empirical chapters and concludes the thesis.

2. *Effect of choice bracketing on risk aggregation*

₁₃₄₆ **2.1 Introduction**

₁₃₄₇ Investors know not to put all their eggs in one basket. Ever since work on modern
₁₃₄₈ portfolio theory (Markowitz, 1952), it has been clear that combining the risk of a
₁₃₄₉ set of individual investments reduces the overall risk of the portfolio of investments.
₁₃₅₀ But what about situations in which it is not clear that a set of investments fit
₁₃₅₁ together as a portfolio? Personal decisions such as buying a car or moving cities are
₁₃₅₂ typically evaluated independently, as are business decisions such as a farm investing
₁₃₅₃ in new cropping technology or a multi-business firm building a mine.

₁₃₅₄ While these decisions are separated in time, they are often not so far apart that
₁₃₅₅ it is easy to learn from past outcomes (and sometimes the outcomes themselves are
₁₃₅₆ unclear). This is because the outcomes of large investments are often delayed. As
₁₃₅₇ such, the decision-maker cannot always use the knowledge of the returns of one
₁₃₅₈ investment when evaluating a subsequent investment. Any results that a farmer
₁₃₅₉ may identify from using a new technology will only become apparent after many
₁₃₆₀ seasons of use. Similarly, it will take many years for a multi-business firm to
₁₃₆₁ begin to estimate whether the output of a mine resulted in the expected return
₁₃₆₂ on investment. These are the decisions that this chapter investigates: sequences
₁₃₆₃ of large risky choices without immediate outcomes.

₁₃₆₄ Risk aggregation is the combination of probability or variance information
₁₃₆₅ (or both) associated with certain outcomes for the purpose of understanding
₁₃₆₆ that information more comprehensively (Bjørnson & Aven, 2019). However, the
₁₃₆₇ psychological literature suggests that this process may be difficult for people to
₁₃₆₈ use. Work on prospect theory (Kahneman & Tversky, 1979) suggests that people's
₁₃₆₉ evaluation of gambles does not conform to expected utility theory and is prone
₁₃₇₀ to framing effects. Specifically, people typically evaluate gambles one by one
₁₃₇₁ (Kahneman & Lovallo, 1993; Rabin & Weizsäcker, 2009; Tversky & Kahneman,
₁₃₇₂ 1981). As such, it is unlikely that people will be able to aggregate risk when they
₁₃₇₃ do not perceive a series of investments as a portfolio. So, what would encourage
₁₃₇₄ people to aggregate risk? The literature on *choice bracketing* (Read et al., 1999)

2. Effect of choice bracketing on risk aggregation

1375 shows that grouping a set of individual gambles together facilitates risk aggregation.
1376 As such, the current work provides two primary contributions. First, this work
1377 is the first to investigate the effect of choice bracketing on risk aggregation in
1378 independent gambles evaluated without immediate returns. Second, this work
1379 introduces novel choice bracketing manipulations.

1380 The earlier work on risk aggregation essentially did the aggregating work for the
1381 participants. For example, experimenters provided participants with an outcome
1382 probability distribution, usually with an explicit indication to group the choices
1383 together, such as by asking for a single decision to be made on a set of identical
1384 gambles. Other work addressed the more realistic situation of a set of independent
1385 gambles. However, most of this work provided participants with the outcomes
1386 of their choices before the subsequent choice. In these paradigms participants
1387 experienced individual outcomes from the eventual outcome distribution of the
1388 gambles, meaning that aggregation was confounded with learning.

1389 As mentioned above, in real-life there is usually a significant delay between
1390 the choice a person or firm makes and the outcome of that choice, and there
1391 are likely to be several interim choices in the meantime. This is especially true
1392 for business executives, who would typically have to wait months or years before
1393 beginning to understand the consequences of their decision, and even then the
1394 outcome may be unclear. However, previous work did not investigate the effect
1395 of choice bracketing on risky choice without feedback. This is surprising, since
1396 choice bracketing is exactly the kind of process that should promote aggregation
1397 in these more realistic decisions. As such, this chapter investigated new ways of
1398 encouraging participants to bracket their risky choices, but with a paradigm that
1399 involves a series of independent choices without feedback. In this way, the paradigm
1400 is more isometric with real-life risky choice.

1401 2.1.1 Multi-play gambles

1402 Despite the difficulties of risk aggregation, people seem to aggregate “naively”
1403 when considering multiple gambles. Samuelson (1963) told of a colleague who

2. Effect of choice bracketing on risk aggregation

1404 rejected a gamble that involved a 50% chance of gaining \$200 and a 50% of losing
1405 \$100, despite the gamble's positive Expected Value (EV). That is, $200 \cdot 0.5 - 100 \cdot 0.5 =$
1406 50. Rejection of a positive EV gamble out of fear of the possible loss is classic loss
1407 aversion. However, the same colleague said he would accept 100 plays of the same
1408 gamble. Samuelson argued that this choice is irrational.¹ Intuitively, it is clear that
1409 over the course of 100 gambles, the positive EV wins out, and a net loss of money
1410 is extremely unlikely. Samuelson's colleague was more risk averse when making a
1411 single decision about one gamble (a *single-play* gamble), than when making a single
1412 decision about multiple (in this case 100) identical gambles (a *multi-play* gamble).²

1413 Wedell and Böckenholt (1994) replicated the Samuelson (1963) anecdote ex-
1414 perimentally with a gamble involving a potential gain of \$100 and a potential loss
1415 of \$50. Participants accepted the multi-play gamble of 100 plays more than the
1416 single-play gamble. This effect has since been replicated with different outcomes
1417 and probabilities, both with hypothetical and real money. Some participants often
1418 require fewer than 10 plays of a previously rejected gamble in order to accept it
1419 (DeKay & Kim, 2005; Keren, 1991; Montgomery & Adelbratt, 1982; Redelmeier
1420 & Tversky, 1992). Other similar studies found a multi-play effect that was in the
1421 predicted direction but not significant (Barron & Erev, 2003; Benartzi & Thaler,
1422 1999; Klos et al., 2005; T. Langer & Weber, 2001). Further, the effect is not seen
1423 when participants do not perceive gamble outcomes as fungible (DeKay, 2011;
1424 DeKay et al., 2006; DeKay & Kim, 2005) or when choice is continuous rather
1425 than discrete (Bristow, 2011).

1426 However, multi-play effects are likely robust, since there is also evidence that
1427 such gambles reduce a variety of cognitive biases. These include common-ratio
1428 effects (DeKay et al., 2006; Keren, 1991; Keren & Wagenaar, 1987), preference
1429 reversals (Wedell & Böckenholt, 1990), ambiguity aversion (H.-H. Liu & Colman,
1430 2009), and the illusion of control (Koehler et al., 1994). Participants are also more

¹Other work suggests that it is consistent with expected utility theory, once certain assumptions are added (e.g., Aloysius, 2007; Ross, 1999). However, a normative discussion is out of the scope of the present work.

²This chapter uses the terminology for gamble types used in Bristow (2011), and Camilleri and Newell (2013).

2. Effect of choice bracketing on risk aggregation

likely to use explicitly provided EVs in multi-play gambles (Li, 2003), show eye movements more congruent with an EV model than single-play gambles (Su et al., 2013), and judge multi-play gambles as riskier (Joag et al., 1990).

People prefer multi-play gambles that are displayed with an aggregated outcome distribution of those gambles than those without (Benartzi & Thaler, 1999; Coombs & Bowen, 1971; DeKay & Kim, 2005; Keren, 1991; Klos, 2013; T. Langer & Weber, 2001; Redelmeier & Tversky, 1992; Venkatraman et al., 2006; Webb & Shu, 2017). This is because these distributions present the probabilities of all the different possible outcomes, so very clearly show the rarity of a loss. Note that this does not seem to hold when returns are calculated as percentages, rather than fixed dollar amounts (Stutzer, 2013); and when participants do not perceive gamble outcomes as fungible (DeKay & Kim, 2005). However, when this effect is demonstrated, the multi-play gamble is usually set up such that its (binomial) outcome distribution shows a relatively low chance of losing any money and a very low chance of losing a lot of money. For instance, Figure 2.1 shows the outcome distribution of the Samuelson (1963) gamble played 10 times. Outcome distributions of this sort do the aggregating work for the participants, making the attractiveness of the multi-play gamble clearer. This work suggests that participants can comprehend and respond to aggregated risk, but that they struggle to compute the aggregation without external help.

2.1.2 Repeated-play gambles

Decisions in real life are usually sequential, and rarely identical as in the multi-play paradigm (cf. Barron & Erev, 2003). That is, people tend to be confronted with individual choices whose outcomes and outcome probabilities are different from one choice to another, and these choices occur at different points in time. In a business setting this can be seen in decisions about whether to invest in new projects; proposals and opportunities differ widely and occur at different times. Managers are not ever simply asked: “here are 10 identical investments to consider; do you want all or none of them?”

2. Effect of choice bracketing on risk aggregation

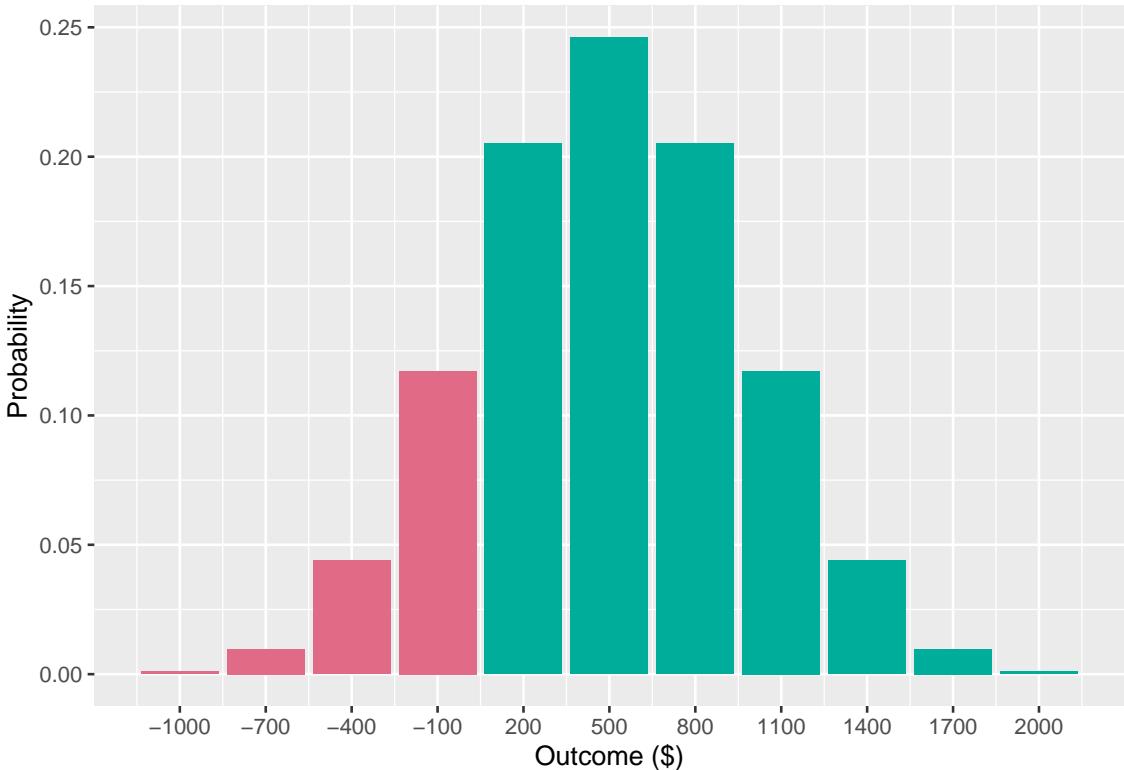

Figure 2.1: The outcome probability distribution of the Samuelson (1963) gamble (50% chance of gaining \$200 and a 50% of losing \$100) played 10 times.

1459 In *repeated-play* (rather than multi-play) gamble paradigms, participants make
1460 decisions about a series of individual gambles. Research using this paradigm found
1461 that people are less risk averse both when outcomes for a series of gambles are
1462 evaluated less frequently and the subsequent decisions are made less frequently
1463 (Bellemare et al., 2005; Beshears et al., 2016; Gneezy & Potters, 1997; Thaler
1464 et al., 1997). People are also less risk averse (for positive EV gambles) when they
1465 receive feedback after each decision or are able to sample from the distribution
1466 of possible outcomes before making a choice (Barron & Erev, 2003; Camilleri &
1467 Newell, 2011, 2013; Hertwig et al., 2004; Jessup et al., 2008; Ludvig & Spetch,
1468 2011; Wulff et al., 2018). Other work found that loss aversion is mitigated when
1469 people are explicitly instructed to consider the options as a part of a portfolio
1470 (Sokol-Hessner et al., 2012; Sokol-Hessner et al., 2009).

1471 These studies are closer to real-life decisions than the multi-play gamble paradigm,
1472 because they involve a set of separate gamble decisions, rather than a single decision

2. Effect of choice bracketing on risk aggregation

about a set of gambles. However, for the most part, the experiments used in the repeated-play gamble literature use various forms of feedback throughout the course of the experiment. That is, participants are shown the outcomes of their gambles before they make more decisions. This paradigm is known as *experience-based choice*. In *description-based choice*, on the other hand, the gamble is simply presented to the participant without any feedback, as in the multi-play gambles above. In real life, people rarely see the immediate outcomes of their risky choices, and even less so in business settings, where any return on investment often takes years to manifest.

Only a limited number of studies have used a repeated-play paradigm without feedback. For instance, Jessup et al. (2008) and Hertwig et al. (2004) investigated the effects of feedback in repeated-play gambles on the weighting of small probabilities, and had a no-feedback control condition. Other work similarly used individual description-based gambles presented sequentially (e.g., Ert & Erev, 2013; Joag et al., 1990). However, these studies did not attempt to facilitate participants' risk aggregation. Haisley et al. (2008) provided limited evidence for facilitating risk aggregation. They gave participants the opportunity to buy five (negative EV) lottery tickets, and either presented them one at a time, or together. Participants bought fewer tickets, when they considered them jointly, thereby maximising EV. However, the experimenters did not specify the outcomes and probabilities of each gamble, meaning that it is unclear if participants understood the independent lotteries as identical or non-identical. This reduces the external validity of the study, as most independent risky choice involves non-identical outcomes and probabilities. In sum, these studies were not designed to research how to facilitate risk aggregation and reduce loss aversion. This chapter is novel because its goal is to facilitate risk aggregation without the experimental artefact of immediate feedback.

2.1.3 Choice bracketing

Research in psychology and economics has identified ways of facilitating risk aggregation by encouraging people to group their choices. Specifically, people aggregate more when they consider the consequences of their choices together

2. Effect of choice bracketing on risk aggregation

1502 (broad bracketing) than when they consider them individually (narrow bracketing;
1503 Read et al., 1999). In multi-play gambles (especially when displayed with an
1504 outcome distribution), choices are inherently bracketed broadly because a single
1505 choice is made about multiple gambles. Similarly, studies that used repeated-play
1506 gambles facilitated risk-tolerance through what can in hindsight be considered broad
1507 bracketing. For instance, when Thaler et al. (1997) presented gamble outcomes
1508 less frequently, they allowed participants to consider longer time increments with
1509 a single evaluation.

1510 Both the original Samuelson (1963) anecdote and its subsequent replications
1511 show that people do have an intuition for aggregation even without the risk being
1512 calculated exactly for them. This chapter tests whether that same intuition can be
1513 elicited and applied across sets of unique bets. What are the minimal conditions
1514 required to encourage aggregation? The multi-play gamble work suggests that
1515 participants can engage in a more intuitive form of aggregation when provided
1516 with the right contextual cues. Investigating the effects of more subtle cues will
1517 help shed light on the cognitive processes underlying choice bracketing. Of course,
1518 the effects of more subtle cues would not eliminate the utility of explicit financial
1519 education, but they will help the design of decision-making contexts to best align
1520 with such instruction.

1521 One way of potentially facilitating risk aggregation is to highlight to participants
1522 the number of total options that are available to them. Sokol-Hessner et al. (2009)
1523 and Sokol-Hessner et al. (2012) reduced risk aversion using lengthy instructions that
1524 encouraged participants to “think like a trader.” This meant considering all the
1525 repeated-play gambles as a portfolio, as opposed to considering them individually.
1526 However, this was quite a strong manipulation that is perhaps unrealistic in real
1527 world. A more subtle cue could involve simply making participants aware that
1528 they are going to be making a series of choices. If people possess an intuitive
1529 understanding of aggregation, as suggested above, then this kind of contextual
1530 cue will also facilitate aggregation.

2. Effect of choice bracketing on risk aggregation

1531 In addition to simply informing participants that they will make a series of choices,
1532 making the choices more readily comparable may facilitate broad bracketing, and
1533 thus risk aggregation. Consider the inverse situation wherein a lack of comparability
1534 between choices may prevent broad bracketing, such as when an executive for a
1535 multi-business firm makes decisions across multiple distinct industries. Of course,
1536 the similarity of decision contexts does not change the maths of risk aggregation,
1537 but may well affect whether people do aggregate risk across decisions. DeKay
1538 and Kim (2005) found that multi-play effects are not seen when choices are not
1539 considered fungible. For instance, participants aggregated across dollar amounts,
1540 but not across patients in a medical decision. As such, people may behave similarly
1541 when considering a set of dissimilar choices if they do not consider them fungible.

1542 There is further suggestive evidence that the similarity of a set of choices to
1543 one another will affect choice bracketing. Choices whose differences are easy to
1544 compare (alignable differences) are weighted heavier than those that are difficult
1545 to compare (Markman & Loewenstein, 2010; Markman & Medin, 1995). Increased
1546 similarity across a set of choices may both highlight the ability for those choices to be
1547 bracketed, and further facilitate risk aggregation through the comparable attributes.
1548 However, it is possible that increased similarity will facilitate risk aggregation even
1549 without a tangible benefit to the underlying calculations. That is, it is possible that
1550 simply manipulating the similarity of financially-irrelevant semantics of a choice set
1551 will make people less risk averse. If so, then this will be by virtue of an implicit risk
1552 aggregation in which the mere awareness of the possibility of a grouping of choices
1553 reduces risk aversion. It is important to investigate the effect of similarity especially
1554 because in managerial settings, executives in multi-business firms will often have
1555 to make comparisons across industries that are hard to compare. For instance,
1556 General Electric currently develops both analytic software products and jet engines
1557 for the military. They had been even more diversified previously, at one stage
1558 simultaneously developing home appliances and owning the NBC television network.

1559 In addition to the similarity between choices, how choices are presented may
1560 affect how easily they are compared, and thus whether or not the multiple subsequent

2. Effect of choice bracketing on risk aggregation

1561 effects listed above would come to fruition. As mentioned above, Haisley et al.
1562 (2008) found a higher degree of EV maximisation when gambles were presented
1563 jointly, rather than separately. Similarly, Hsee et al. (1999) found that people's
1564 choices were affected by whether they viewed the attributes of the choices separately
1565 or jointly. Their *evaluability hypothesis* suggests that attributes that are difficult to
1566 evaluate will have a greater impact on joint presentation than separate presentation.
1567 Joint presentation is a form of broad bracketing because it forces a participant
1568 to view of all the components of a decision together. Participants may therefore
1569 be more likely to consider aggregating the risk involved in a set of choices when
1570 all those choices are in view. Joint presentation potentially reduces the working
1571 memory load otherwise needed to maintain that set of choices. As such, it is quite
1572 possible that a combination of highly similar choices, presented jointly will lead to
1573 the highest likelihood of broad bracketing, and thus risk aggregation.

1574 Moher and Koehler (2010) replicated Gneezy and Potters (1997), but separately
1575 manipulated the number of gambles seen per trial and feedback frequency. They
1576 found that participants were less risk averse when viewing a set of three gambles
1577 per trial, than when viewing only one. However, they only found this effect with
1578 a set of identical outcomes. When outcomes were non-identical, there was no
1579 effect of presentation. However, participants were always presented with gamble
1580 outcomes for each trial, so it is unclear to what extent this influenced participants'
1581 ability to bracket broadly. In fact, when seeing gambles separately, participants
1582 were less risk averse when receiving feedback for each trial, compared to every
1583 three trials. Testing a presentation manipulation without the confound of feedback
1584 will help to clarify this effect.

1585 2.1.4 Internal capital market investment context

1586 Executives of large, successful firms are often viewed as fearless risk-takers who
1587 take on risky projects to generate innovation and growth. However, the available
1588 evidence suggests that executives do not view themselves that way (March & Shapira,
1589 1987; Swalm, 1966). Executives typically evaluate multiple investments over time.

2. Effect of choice bracketing on risk aggregation

1590 Risk aggregation is sensible when investments are only partially correlated (i.e., the
1591 success of one does not influence the success of another). It is sensible to take on a
1592 set of risky investments with positive EV, where each investment has some chance
1593 of loss, because those that succeed will make up for those that failed. These benefits
1594 are well-known in stock market investment settings, thanks to Nobel laureate Harry
1595 Markowitz's work on modern portfolio theory (1952).

1596 However, it is unclear whether the general public and even business managers
1597 use this concept, due to the extent of risk aversion in both those populations (e.g.,
1598 March & Shapira, 1987; Tversky & Kahneman, 1992). In fact, executives treat
1599 risk like the rest of us; they view investments one at a time, are risk averse in
1600 the domain of gains, and are risk seeking in the domain of losses (Lovallo et al.,
1601 2020; MacCrimmon et al., 1986; Swalm, 1966). However, it is understandable
1602 why risk aggregation is foreign to most people; outside of an investment portfolio
1603 selection situation, it is unlikely for people to spontaneously group a selection of
1604 individual risky choices. Usually in life, people encounter risky choices sequentially,
1605 and so the risk of each individual choice is more salient than the aggregated risk
1606 of an arbitrary combination of choices.

1607 Lovallo et al. (2020) show that executives treat investments within their own
1608 company in isolation. In multi-business firms, the managers of each business unit
1609 often make the investment decisions about individual projects. As such, they often
1610 do not consider the scope of their decisions in the context of the entire company. For
1611 instance, Nobel laureate Richard Thaler offered 25 division managers working for the
1612 same firm a hypothetical investment that involves a 50% chance of gaining \$2 million
1613 for the company and a 50% chance of losing \$1 million (1999). Only three managers
1614 said they would accept the investment. However, the CEO indicated that he would
1615 have clearly preferred managers to accept all the investments. To each middle-
1616 manager, the choice represents a risk of loss for their division and potentially their
1617 job, whereas for the CEO the entire portfolio of choices represents a worthwhile risk.

1618 This chapter investigates risky choice in the context of business project in-
1619 vestment internal to a company because this is a real-world context where choice

2. Effect of choice bracketing on risk aggregation

bracketing is important and currently under-appreciated (Lovallo et al., 2020). The participants in these experiments were taken from a population that does not have extensive managerial experience. However, in such a population a lack of risk aggregation is most likely more common, and the variables used here are readily applicable to the financial decisions that laypeople make. For instance, one of the real-world applications of the choice bracketing literature has been to use outcome distributions and increased time horizons to encourage investment in high risk, but high EV, retirement funds (e.g., Benartzi & Thaler, 1999). Otherwise, people typically prefer low risk, low EV, funds. Further, using laypeople eliminates potential differences in prior experience with the management-based decision-context. Upcoming research will focus on managers with context-specific experience to investigate the effects of that experience.

2.2 Experiment 1

Experiment 1 investigated the effect of three choice bracketing manipulations on risky choice in hypothetical capital allocation scenarios. Previous research had low ecological validity because of the use of multi-play paradigms or feedback. In this experiment, the risky choice task was a description-based repeated-play paradigm. This means that participants had to make a choice about whether to accept a number of different hypothetical investments, but were not provided with the outcome of their choices after each decision. The variables of interest were the similarity of the choices, whether the choices were presented together or separately, and whether participants were aware of the number of choices that they would be making.

The values and probabilities of the gambles were set up such that each individual gamble, as well as the aggregation of all the gambles, would be attractive to a rational agent interested in maximising EV. As such, the key dependent measure was the proportion of risky choices participants accepted.

2. Effect of choice bracketing on risk aggregation

1646 Previous research suggests that people will be willing to make more risky
1647 choices when explicitly told to bracket their choices (Sokol-Hessner et al., 2012;
1648 Sokol-Hessner et al., 2009). Therefore, Experiment 1 tested the following:

1649 **Hypothesis 2.1—Awareness main effect.** Participants that know how many
1650 projects to expect will make more risky choices than participants that are unaware.

1651 Further, previous work suggests that joint presentation is a form of broad
1652 bracketing (e.g., Hsee et al., 1999; Moher & Koehler, 2010). Therefore, Experiment 1
1653 tested the following:

1654 **Hypothesis 2.2—Presentation main effect.** Participants will make more risky
1655 choices when seeing projects jointly than when seeing them separately.

1656 Similarity of options has also been shown to affect the way people bracket their
1657 choices (e.g., DeKay & Kim, 2005). Therefore, Experiment 1 tested the following:

1658 **Hypothesis 2.3—Similarity main effect.** Participants that see projects from
1659 the same industry will make more risky choices than participants that see projects
1660 from different industries.

2.2.1 Method

2.2.1.1 Participants

1663 One hundred and ninety-eight people (82 female) were recruited from the online
1664 recruitment platform Prolific. Participants were compensated at a rate of £5 an
1665 hour. The average age was 32.52 ($SD = 11.42$, $min = 18$, $max = 69$). Participants
1666 reported an average of 7.01 ($SD = 9.1$, $min = 0$, $max = 42$) years of work in a
1667 business setting, and an average of 1.7 ($SD = 2.85$, $min = 0$, $max = 20$) years of
1668 business education. The mean completion time was 12.04 ($SD = 11.29$, $min = 3.1$,
1669 $max = 112.4$) minutes. Table 2.1 shows the between-subjects condition allocation.

2. *Effect of choice bracketing on risk aggregation*

Table 2.1: Experiment 1 group allocation.

Similarity	Awareness	N
High	Aware	53
High	Naive	53
Low	Aware	47
Low	Naive	45
Total	-	198

1670 **2.2.1.2 Materials**

1671 **2.2.1.2.1 Instructions** Participants were told to imagine that they are executives in a large company and that they will need to decide about investing in a number of hypothetical business projects. The appendix shows these instructions
1674 in Figure A.1.

1675 **2.2.1.2.2 Risky investment task** Participants saw 10 short descriptions of
1676 business projects, and were asked whether they would invest in that project or
1677 not. Each description included the name of the hypothetical business, the amount
1678 they forecast the project to cost, the amount the project is forecast to make, and
1679 probabilities for these forecasts. The project values were selected so that the
1680 projects appeared attractive when aggregated, and unattractive when segregated
1681 (see T. Langer & Weber, 2001). These values were different for each project, but
1682 followed a set of constraints for each project's EV and the probability of any loss
1683 given the outcome distribution of all 10 projects ($P(\text{loss}_{\text{aggregated}})$). Further, there
1684 was a constraint on the gambles' loss aversion coefficient (λ), which is a measure of
1685 people's greater sensitivity to losses compared to gains. The constraints were:

- 1686 1. $\text{EV} > 0$;
- 1687 2. $\lambda < 2.25$; and
- 1688 3. $P(\text{loss}_{\text{aggregated}}) < 0.1$.

2. Effect of choice bracketing on risk aggregation

Refinera is a business in your company that proposes to construct an oil well project, which they forecast will cost \$40 million. If the project succeeds, forecasts show the company would make \$240 million. Research suggests that there is a 20% chance of the project succeeding. Therefore, there is 20% chance of gaining \$200 million and a 80% chance of losing \$40 million on the investment.

Would you invest in the project?

*

Yes No

Continue

Figure 2.2: Example of a project choice display in Experiment 1. Border added for clarity.

1689 As such, each project cannot be considered to be a loss in terms of expected
1690 value, but also would not be an easy choice for investment, because of the low λ
1691 (made to be lower than the median loss aversion coefficient calculated in Tversky &
1692 Kahneman, 1992). Further, since people are especially sensitive to loss probabilities
1693 (Kahneman & Tversky, 1979; Zeisberger, 2020), an arbitrarily low $P(\text{loss}_{\text{aggregated}})$
1694 was chosen to make investment in the complete set of projects seem attractive. The
1695 actual probability of a loss given the outcome distribution used in the experiment
1696 was 0.09. This was calculated by summing all probabilities in the Poisson binomial
1697 distribution whose outcomes were less than zero. For comparison, $P(\text{loss}_{\text{aggregated}})$
1698 = 0.17 for 10 plays of the Samuelson (1963) gamble. The highest probability of a
1699 loss for any single gamble ($P(\text{loss}_{\text{single}})$) was 0.80. Figure 2.2 shows an example
1700 of a description of a project in this task.

1701 In the high similarity condition, these project descriptions were all about one
1702 type of project (in this case an oil well project) and were all from the same business.
1703 In the low similarity condition, each project was from a different industry. In the
1704 joint presentation condition, the 10 projects were all displayed on the one webpage,
1705 whereas in the separate presentation condition each was displayed on a different
1706 webpage. Participants in the aware condition saw the display shown in Figure 2.3

2. *Effect of choice bracketing on risk aggregation*

You will now see 10 projects. Decide whether you would like to invest in each one.

Continue

Figure 2.3: The display seen by those in the aware condition of Experiment 1. Border added for clarity.

1707 before their separate presentation display. Those in the naive condition simply
1708 proceeded without this message. The financial and probability values were identical
1709 regardless of condition, and the order of each set of 10 projects was randomised.

1710 Although the project descriptions were succinct, and the decisions in the
1711 task were made quickly, they reflect real decisions in businesses in critical ways.
1712 Companies that consider their forecast estimates probabilistically (i.e., do not
1713 simply use the most likely estimate as the only estimate) do frame their options
1714 as likelihoods of certain monetary outcomes.

1715 **2.2.1.2.3 Outcome distribution decision** Participants were asked if they
1716 would invest in the last 10 projects they saw and were provided with a graph of the
1717 outcome probability distribution of the 10 projects. The appendix shows this graph
1718 in Figure A.2. A coding error was discovered after collecting data. This was an error
1719 in the generation of gambles, which meant that the outcome distribution decision
1720 data could not be used. Therefore, the effect of outcome distribution will not be
1721 discussed until Experiment 2, which fixed this issue. Appendix A.1.2.2 presents an
1722 analysis of this data, and describes the coding error and its implications.

1723 **2.2.1.2.4 Follow-up gambles** Participants were shown four further sets of
1724 gambles (11 total) that functioned to check participant attention and replicate
1725 the gambles from Samuelson (1963) and Redelmeier and Tversky (1992). See
1726 Appendix A.1.1.1.3 for details.

1727 **2.2.1.3 Procedure**

1728 Participants read the instructions and completed the risky investment task, first
1729 in the separate presentation condition, and then in the joint condition. They then

2. Effect of choice bracketing on risk aggregation

1730 made the outcome distribution decision and responded to the 11 follow-up gambles.

1731 2.2.2 Results

1732 2.2.2.1 Project choice

1733 A three-way ANOVA was conducted to investigate the effects of similarity,
1734 awareness, and presentation on the proportion of participants' decision to invest
1735 in the 10 projects. As seen in Figure 2.4, participants invested more when they
1736 were told that there will be 10 projects, compared to when they were not told
1737 this, $F(1, 194) = 9.52, p = .002, \hat{\eta}_p^2 = .047$. As seen in Figure 2.5, participants
1738 invested more when viewing the projects jointly, compared to when they viewed
1739 them separately, $F(1, 194) = 28.14, p < .001, \hat{\eta}_p^2 = .127$. Although there was no
1740 main effect of similarity, $F(1, 194) = 1.63, p = .204, \hat{\eta}_p^2 = .008$, the interaction
1741 between similarity and presentation was significant, $F(1, 194) = 4.31, p = .039,$
1742 $\hat{\eta}_p^2 = .022$ (see Figure 2.6). Specifically, the presentation effect was stronger in
1743 the high similarity condition, $\Delta M = 0.07$, 95% CI [0.04, 0.09], $t(194) = 5.29,$
1744 $p < .001$, than in the low similarity condition, $\Delta M = 0.03$, 95% CI [0.00, 0.05],
1745 $t(194) = 2.06, p = .041$. These findings suggest that it is possible to facilitate risk
1746 aggregation with subtle choice bracketing manipulations.

1747 2.2.2.2 Trial-by-trial analysis

1748 Exploratory analyses were conducted into the possible effects of the manipu-
1749 lations on a trial-by trial basis. The appendix shows the data for all conditions
1750 (see Figure A.3). The key findings are in the separate presentation. As Figure 2.7
1751 shows, in the separate condition people are more likely to accept projects over the
1752 10 trials, but this interacts with awareness, $b = 0.04$, 95% CI [0.01, 0.08], $z = 2.32,$
1753 $p = .021$. Specifically, the relationship between choice and trial is stronger in the
1754 aware condition, $b = 0.11$, 95% CI [0.06, 0.16], $z = 4.54, p < .001$, than in the
1755 naive condition, $b = 0.03$, 95% CI [-0.03, 0.08], $z = 1.01, p = .311$. It seems that
1756 participants that were told the total number of projects became less risk averse
1757 as the experiment proceeded, regardless of the gamble values.

2. Effect of choice bracketing on risk aggregation

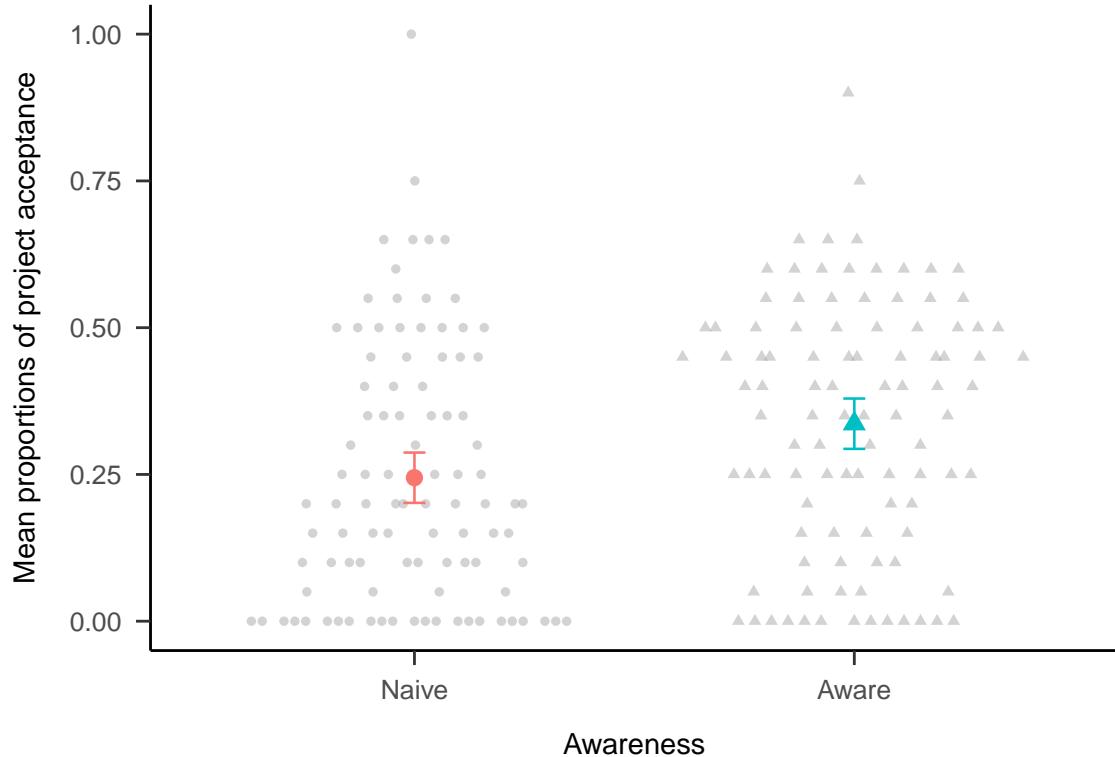

Figure 2.4: Mean proportions of decisions to invest in each set of 10 projects, by awareness condition. Error bars represent 95% confidence intervals. Raw data are plotted in the background.

2.2.3 Discussion

Experiment 1 found evidence for most of the hypotheses. Specifically, people made more risky choices when considering those choices jointly on the same page, compared to on separate pages; and when they knew how many choices were in the set. Further, the results showed an interaction between project similarity and presentation. Exploratory analyses showed that participants' risk aversion decreased as they proceeded through the trials, but only when participants were aware of the number of projects.

2.2.3.1 Presentation effect

The presentation effect may be a result of one of two mechanisms. A mathematical aggregation explanation would mean that participants are combining the gambles into a mental representation of the probability distribution and then deciding based on the attractiveness of that distribution. A joint presentation of

2. Effect of choice bracketing on risk aggregation

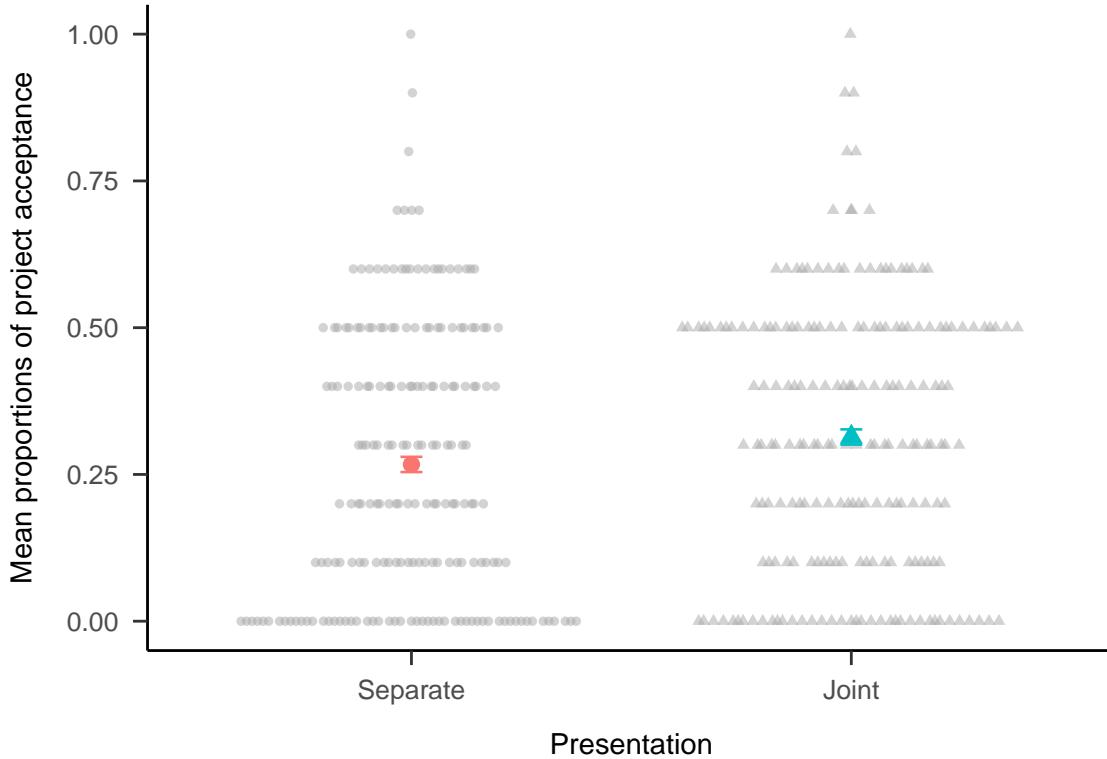

Figure 2.5: Mean proportions of decisions to invest in each set of 10 projects, by presentation condition. Error bars represent 95% confidence intervals. Here, however, the intervals are so narrow that they are sometimes obscured by the mean indicators in the plot. Raw data are plotted in the background.

choices would facilitate this combination. On the other hand, people may also be using a sort of naive aggregation process when they are encouraged to group their choices together. A naive aggregation explanation would suggest that participants in the joint condition are simply more likely to realise that a few big wins could offset a few losses. Participants could have been encouraged by the joint display to consider the set of projects together. This could then lead to the conclusion that investing in a higher number of gambles might mean that the gains of some projects will pay off the losses of the other projects.

2.2.3.2 Awareness effect

Experiment 1 found that participants that viewed the projects separately were more likely to invest in the projects as the trials went on, regardless of the actual gambles. Having an awareness of the total number of projects in the set could increase the likelihood that participants would naively aggregate. Specifically,

2. Effect of choice bracketing on risk aggregation

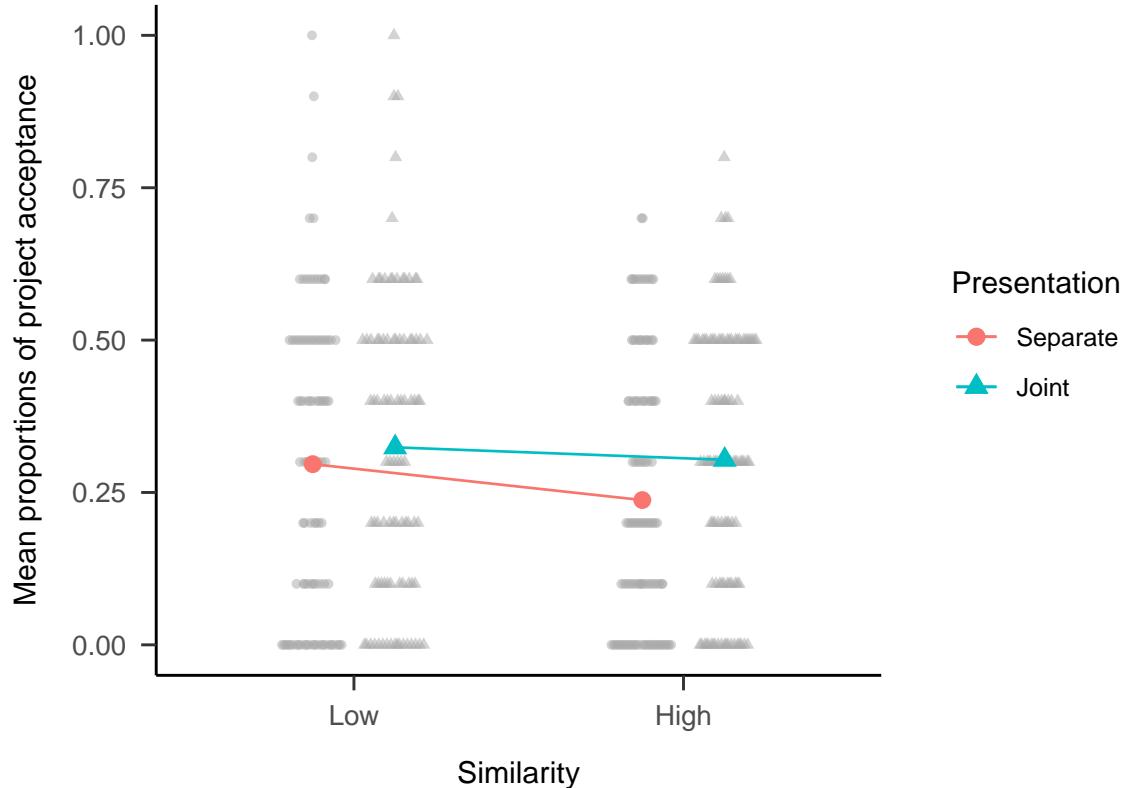

Figure 2.6: Mean proportions of decisions to invest in each set of 10 projects, by similarity and presentation conditions. In mixed factorial designs, error bars cannot be used to make inferences by “eye” across all conditions. Therefore, error bars are not included. Raw data are plotted in the background.

knowing the number of total projects might increase the salience of the idea that the gains of some projects will offset the losses of others, because it reinforces a focus on the entire set. Another possibility is that participants had a certain aspiration level (Lopes, 1996) that they were attempting to reach. This might mean that they invested more as the task proceeded after realising that the gambles were not becoming significantly more favourable. Barron and Erev (2003, p. 219) specifically did not tell participants about the number of gambles they would experience to “avoid an ‘end of task’ effect (e.g. a change in risk attitude).” Barron and Erev (2003) provided participants with feedback, but this should not be necessary for an aspiration level explanation since participants only need to be aware of the potential for certain gains.

This result may also be due to a Gambler’s fallacy effect or the law of small numbers. This effect is characterised by people’s expectation of a pattern to follow

2. Effect of choice bracketing on risk aggregation

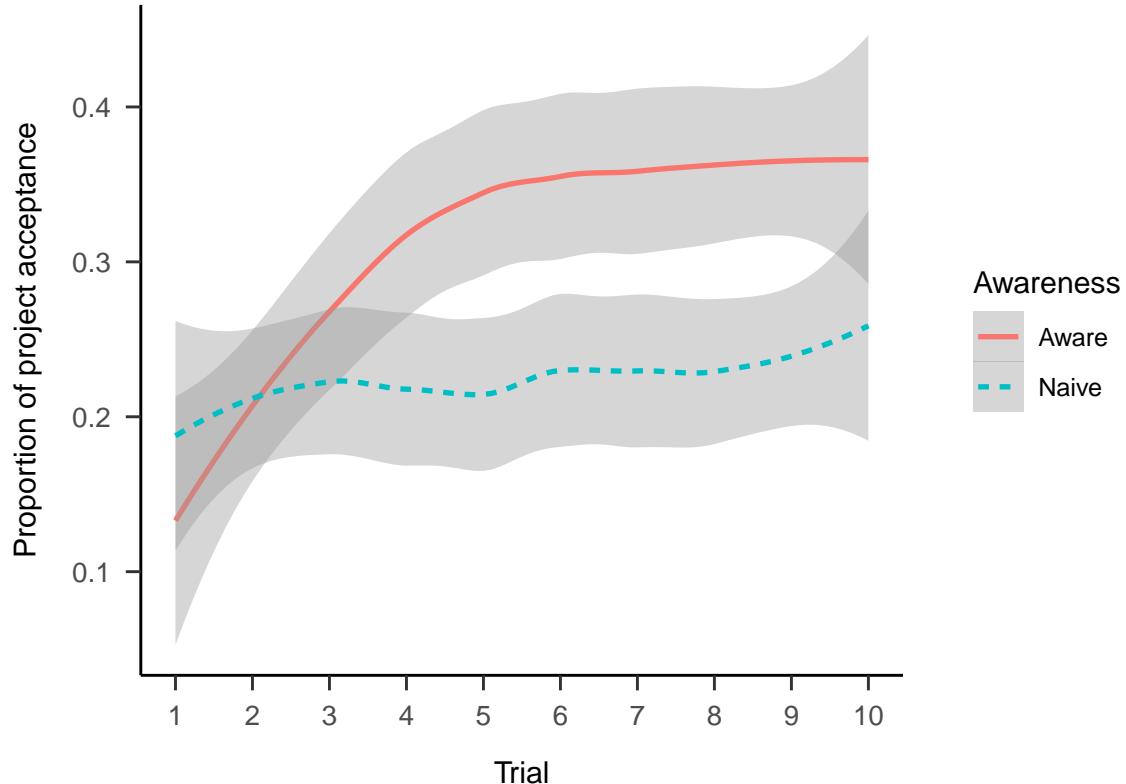

Figure 2.7: Proportion of project acceptance in the separate presentation condition, by trial and awareness conditions. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals.

the underlying distribution of the function that generates each component. For instance, someone observing the results of a coin flip that look like HTTHHTTTT might anticipate that the likelihood of “heads” is higher than that of “tails,” despite the actual likelihood being 50% for either. This effect occurs in sequential decision-making, so may be relevant for the repeated-play decisions in Experiment 1. Barron and Leider (2010) found that the gambler’s fallacy (in a roulette prediction task) emerges when information about past outcomes was displayed sequentially, but not when it is displayed all at once. Haisley et al. (2008) found evidence for the gambler’s fallacy with a repeated-play gamble paradigm. As such, it is possible that an effect such as the Gambler’s fallacy can explain the effect of the awareness manipulation. That is, participants may have thought that after a few gambles that they considered risky, the last ones were more likely to materialise. Further, this would be more likely to occur for those that knew the total number of projects,

2. Effect of choice bracketing on risk aggregation

1810 because they knew when the sequence was approaching its end.

1811 2.2.3.3 Similarity effect

1812 Experiment 1 did not find a main effect of similarity in the individual choice
1813 data as predicted in Hypothesis 2.3. Instead, choice similarity interacted with
1814 the presentation condition. This interaction is harder to explain since it was not
1815 hypothesised. In fact, the results seem to suggest the opposite to what was originally
1816 expected. Initially, it was predicted that people would be less risk averse in the
1817 high similarity condition, due to the better ability to consider the isolated projects
1818 as a grouped set. Similarity was thought to act as a broad bracket, and therefore
1819 increase aggregation. That is, it was expected that seeing a set of similar projects
1820 would help participants aggregate risk when seeing them separately, more than
1821 when projects are dissimilar. Instead, project acceptance was actually numerically
1822 higher in the low than in the high similarity condition ($\Delta M = -0.06$, 95% CI
1823 $[-0.12, 0.00]$, $t(228.14) = -1.83$, $p = .068$) when projects were presented separately,
1824 averaging over awareness conditions.

1825 There was no significant difference between similarity conditions regardless
1826 of presentation condition. However, allocations were significantly higher in the
1827 joint presentation condition than in the separate condition for both high and low
1828 similarity. The interaction seems to have been found due to the larger difference in
1829 the high similarity condition. Perhaps the ability to aggregate risk when projects
1830 are presented together is more made more salient when projects are similar.

1831 Specifically, the interaction seems to be driven by the separate high similarity
1832 condition being lower, rather than by the joint high similarity being higher, as
1833 would have been expected. As such, participants could have been engaged in a
1834 naive *diversification*, rather than a naive aggregation. In “true” diversification,
1835 people would choose a set of projects that are partially (and ideally negatively)
1836 correlated, as per Markowitz (1952). However, in reality people that intend to
1837 diversify only seem diversify naively, meaning that they neglect co-variation when
1838 diversifying (e.g., Hedesstrom et al., 2006). Instead, they only seem to be looking

2. Effect of choice bracketing on risk aggregation

1839 for variety, rather than diversification in the strict sense. This *diversification bias*
1840 is also seen in product choices (Read & Loewenstein, 1995).

1841 In Experiment 1, participants may have considered the high similarity condition
1842 as a sign that the set of projects may not be sufficiently “diversified.” However, this
1843 explanation would also predict the joint presentation condition to be lower in the
1844 high similarity condition. So, perhaps when in the separate condition, participants
1845 were constantly thinking that they might be getting a different project in the next
1846 display, so rejected more projects because of the lack of diversification, but not
1847 realising that they would not be getting any other type of project. Those in the
1848 joint presentation, on the other hand, were able to see all ten projects, so already
1849 knew that there were no other projects in the set, and so were less likely to reject
1850 projects on the basis of the hope for different projects in the future.

1851 2.2.3.4 Limitations

1852 This experiment had two major limitations. First, proper counterbalancing was
1853 not used in the high alignment project domain, nor in the order of the within-subjects
1854 manipulation of presentation. As such, it is unclear what role these elements played
1855 in the results, especially in the presentation condition, in which participants always
1856 saw the separate condition first. Second, as mentioned above in Section 2.2.1.2.3,
1857 there was a mistake in the generation of the gamble values that meant that the
1858 individual gambles did not correspond with the distribution that participants saw.
1859 Both of these limitations were addressed in Experiment 2.

1860 2.3 Experiment 2

1861 Experiment 2 investigated the effect of presentation, awareness, and distribution
1862 on project choice. For the distribution manipulation, half of the sample saw an
1863 outcome probability distribution as in the previous literature (e.g., Redelmeier &
1864 Tversky, 1992; Webb & Shu, 2017) to determine their risk aversion when the gambles
1865 are explicitly aggregated. In contrast to most of the repeated-play choice literature,
1866 each choice was presented without subsequent feedback. Further, in contrast to

2. Effect of choice bracketing on risk aggregation

1867 Experiment 1, the distribution were displayed alongside each gamble, as opposed
1868 to only at the very end. This is an important manipulation because finding out
1869 whether it is effective will 1. add to the understanding of the conditions necessary
1870 for mathematical aggregation (beyond a mere intuitive sense of aggregation), and
1871 2. suggest new ways to encourage aggregation in real-world applications.

1872 In past work, participants were shown ordinary binomial distributions, since
1873 multi-play gambles are identical. However, there has not been an investigation of
1874 *non-identical* gamble distributions in this context. Doing this requires using a *Pois-*
1875 *son* binomial distribution, which allows for multiple trials with different probabilities.

1876 Further, Experiment 2 addressed potential order effects in Experiment 1 by
1877 manipulating all the main variables between-subjects. Manipulating presenta-
1878 tion between-subjects, removes the potentially confounding factor of reduced risk
1879 aversion over time.

1880 Experiment 2 again tested Hypotheses 2.1, and 2.2, from Experiment 1. Further,
1881 following the finding in Experiment 1 that participants in the aware condition
1882 seemed to become more risk-taking as the experiment progressed, Experiment 2
1883 tested the following:

1884 **Hypothesis 2.4—Interaction of trial number and awareness.** Participants
1885 will make more risky choices as the trials progress, but only when they are aware of
1886 the total number of projects in the set.

1887 Further, multi-play gambles with outcome distributions have been shown to
1888 reduce risk aversion compared to multi-play gambles without distributions (e.g.,
1889 Redelmeier & Tversky, 1992; Webb & Shu, 2017). Therefore, Experiment 2
1890 tested the following:

1891 **Hypothesis 2.5—Distribution effect.** Participants will make more risky choices
1892 when presented with an aggregated outcome distribution than when making the
1893 same decisions individually.

2. Effect of choice bracketing on risk aggregation

Table 2.2: Experiment 2 group allocation.

Awareness	Distribution	Presentation	N
Aware	Absent	Separate	40
Naive	Absent	Joint	41
Naive	Absent	Separate	41
Naive	Present	Separate	42
Total	-	-	164

2.3.1 Method

2.3.1.1 Participants

One hundred and sixty-four people (51 female) were recruited from the online recruitment platform Prolific. Participants were compensated at a rate of £5 an hour. The average age was 26.39 ($SD = 8.63$, $min = 18$, $max = 72$). Participants reported an average of 2.55 ($SD = 5.34$, $min = 0$, $max = 43$) years of work in a business setting, and an average of 1.67 ($SD = 2.94$, $min = 0$, $max = 20$) years of business education. The mean completion time was 6.53 ($SD = 5.15$, $min = 1.18$, $max = 39.93$) minutes. Table 2.2 shows the between-subjects condition allocation. Appendix A.2.1.1.1 describes the power analysis conducted to arrive at this sample size.

2.3.1.2 Materials

2.3.1.2.1 Instructions Participants were shown the same instructions as in Experiment 1 (see Section 2.2.1.2.1).

2.3.1.2.2 Risky investment task Participants saw a similar display to the one in Experiment 1 (see Section 2.2.1.2.2), but with new gamble values, in order to fix the mistake in the Experiment 1 gamble value calculation (detailed in the appendix Section A.1.2.2).

The presentation and awareness manipulations were as in Experiment 1. However, in the distribution-present condition participants saw the outcome probability

2. Effect of choice bracketing on risk aggregation

¹⁹¹⁴ distribution of all the projects alongside the description, rather than after all the
¹⁹¹⁵ projects were seen (see Figure 2.8).

¹⁹¹⁶ **2.3.1.2.3 Follow-up** Participants were asked how many projects they think
¹⁹¹⁷ they saw, whether they were willing to accept all or none of the projects, and
¹⁹¹⁸ how many they would be willing to accept if they had to choose a number.
¹⁹¹⁹ Appendix A.2.1.2.1 shows these questions.

1920 **2.3.1.3 Procedure**

¹⁹²¹ Participants read the instructions and completed the risky investment task in
¹⁹²² their respective conditions. After seeing the individual projects, participants were
¹⁹²³ then asked the three follow-up questions.

1924 **2.3.2 Results**

1925 **2.3.2.1 Project investment**

¹⁹²⁶ The project investment data were analysed as proportions of choice per partici-
¹⁹²⁷ pant, as in Experiment 1. Each experimental condition was compared to the same
¹⁹²⁸ control condition (separate presentation, naive awareness, and distribution absent).
¹⁹²⁹ Figure 2.9 shows these data. The difference between presentation conditions was not
¹⁹³⁰ significant, $F(1, 80) = 0.00, p > .999, \hat{\eta}_p^2 = .000$. Similarly, the difference between
¹⁹³¹ awareness conditions was not significant, $F(1, 79) = 0.44, p = .508, \hat{\eta}_p^2 = .006$.
¹⁹³² However, those that saw a distribution chose to invest significantly more
¹⁹³³ (51.19%) than those that did not see a distribution (39.02%), $F(1, 81) = 4.46,$
¹⁹³⁴ $p = .038, \hat{\eta}_p^2 = .052$.

¹⁹³⁵ Further, as Figure 2.10 shows, it doesn't seem as if the previous awareness
¹⁹³⁶ by trial effect was replicated.

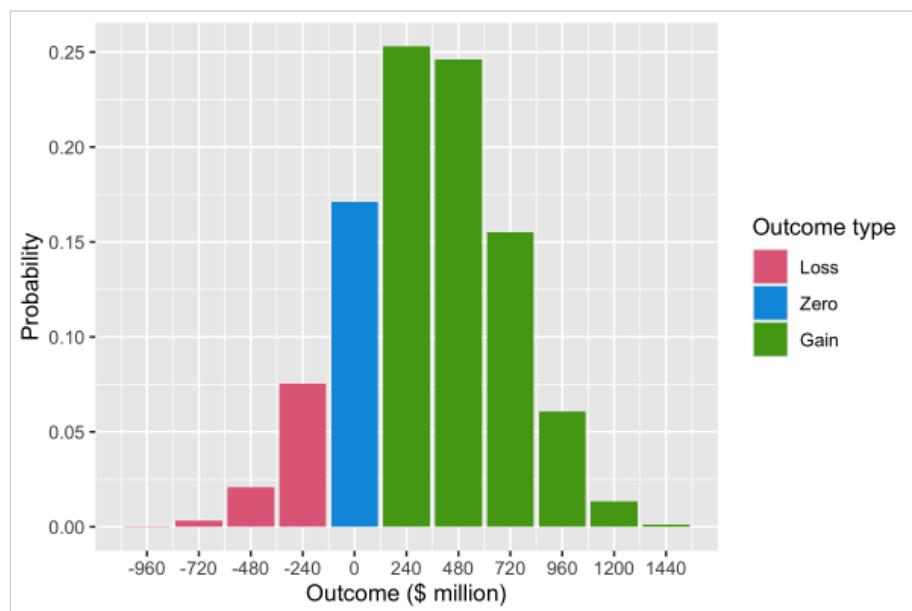

1937 **2.3.2.2 Follow-up**

¹⁹³⁸ The portfolio choice data from both the number and binary questions were
¹⁹³⁹ congruent with the above, finding that those in the distribution condition were
¹⁹⁴⁰ more likely to invest (see Appendix A.2.2).

2. Effect of choice bracketing on risk aggregation

Below is the probability distribution of final outcomes if all projects were chosen.

The numbers on the x-axis (labelled 'Outcome') represent the final amounts of money possible if you chose to invest in all the projects. The numbers on the y-axis (labelled 'Probability') represent the likelihoods of each of the possible outcomes. Negative final outcomes (losses) are shown in red, positive final outcomes (gains) are shown in green, and a final outcome of zero (no loss or gain) is shown in blue.

Indicate below whether you would invest in the following:

Refinera is a business in your company that proposes to construct an oil well project, which they forecast will cost \$40 million. If the project succeeds, forecasts show the company would make \$240 million. Research suggests that there is a 30% chance of the project succeeding. Therefore, **there is 30% chance of gaining \$200 million and a 70% chance of losing \$40 million on the investment.***

Figure 2.8: An example of a display seen by those in the separate distribution-present condition of Experiment 2.

2. Effect of choice bracketing on risk aggregation

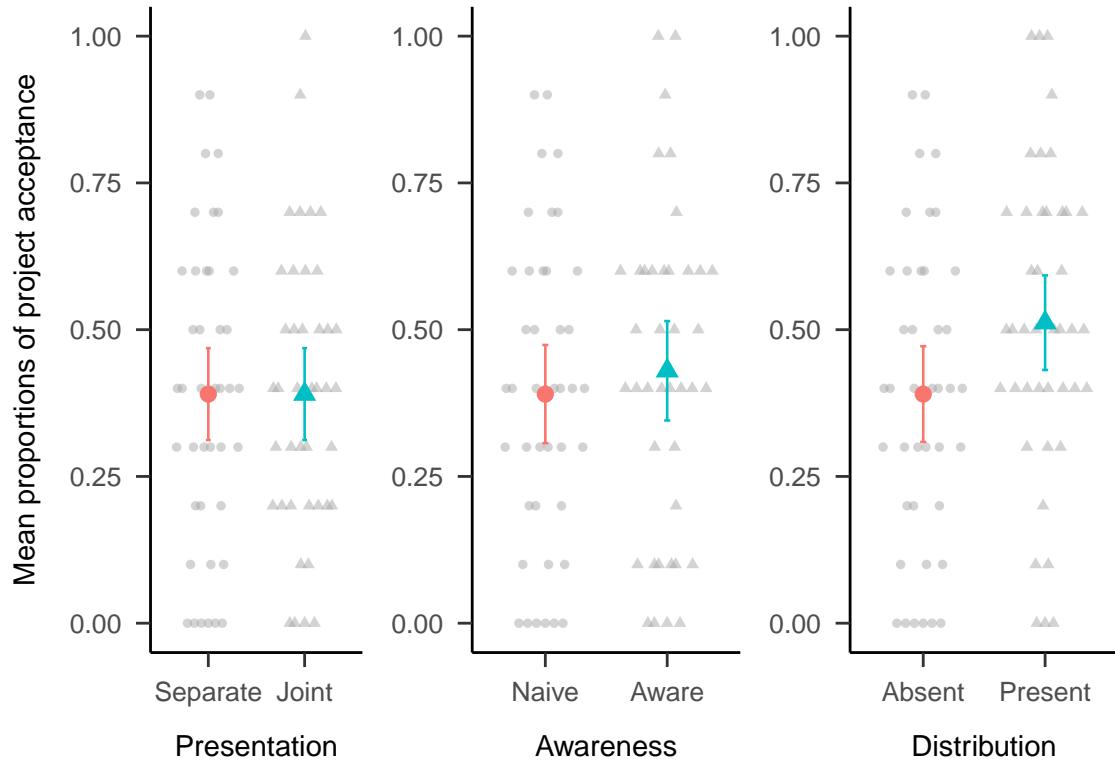

Figure 2.9: Mean proportion of project acceptance for the presentation, awareness, and distribution effects. The condition on the left of each effect is the reference condition (separate presentation, naive awareness, distribution absent). As such, it is identical for the three effects. Error bars represent 95% confidence intervals. Raw data are plotted in the background.

2.3.3 Discussion

1941 Experiment 2 found support for Hypothesis 2.5). Seeing an outcome distribution
 1942 of a business project portfolio had a strong effect on participants' decision-making.
 1943 Participants indicated that they would invest in more projects and were more likely
 1944 to indicate that they would invest in the entire portfolio. However, the awareness
 1945 and presentation effects found in Experiment 1 (see Section 2.2.2) did not replicate.
 1946

1947 These findings provide evidence for choice bracketing. That is, people do
 1948 seem to be primarily considering gambles one at a time. Further, these findings
 1949 suggest that that the main bottleneck for appropriately aggregating a set of gambles
 1950 is a computational one. That is, people simply cannot mentally combine the
 1951 outcomes and probabilities in a way that sufficiently approximates the outcome
 1952 distribution display.

2. Effect of choice bracketing on risk aggregation

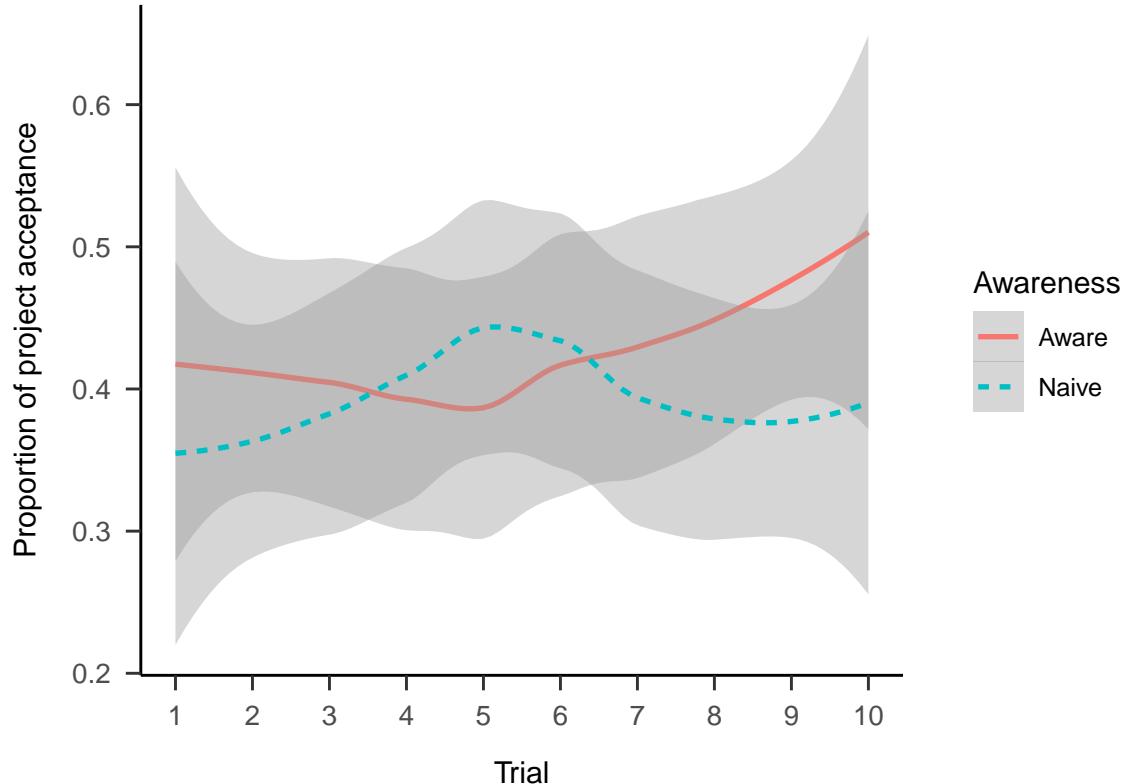

Figure 2.10: Mean project acceptance for separate presentation, distribution absent condition, by awareness and trial. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals.

1953 The lack of replication of the awareness and presentation effects provides evidence
 1954 against a naive aggregation account of the distribution effect. Specifically this
 1955 suggests that the distribution effect is a result of a lack of ability to mathematically
 1956 combine risk, rather than naive aggregation. If some of the bottleneck was
 1957 attributable to a lack of realisation that the individual gambles could be grouped
 1958 together, then the effects from Experiment 1 should have replicated. Instead it seems
 1959 that even when people have an opportunity to consider an entire set of risky choices
 1960 together (and consider that the gains may outweigh the losses), they do not do this.

1961 In Experiment 2, all the gambles came from the same domain. This was
 1962 done to attempt to replicate the relevant effects from Experiment 1. However,
 1963 there could have been something about that particular domain that led to the
 1964 lack of replication. A follow-up experiment addressed this issue by presenting
 1965 participants with 20 gambles from 10 different industries and still did not replicate

2. Effect of choice bracketing on risk aggregation

¹⁹⁶⁶ the awareness effect (see Appendix A.4).

¹⁹⁶⁷ **2.4 General discussion**

¹⁹⁶⁸ When making one decision about a series of risky choices, it is clear that people
¹⁹⁶⁹ have an intuitive sense of the advantages of risk aggregation (e.g., Samuelson, 1963).
¹⁹⁷⁰ However, because risky choices are typically made one at a time in the real world,
¹⁹⁷¹ this chapter aimed to identify whether (and how) this intuition could be leveraged
¹⁹⁷² in this more realistic scenario. Overall, there was little evidence that subtle cues
¹⁹⁷³ could tap into this intuitive advantage of risk aggregation, and clear visualisations
¹⁹⁷⁴ of outcome distributions were needed to assist people's risk aggregation. This
¹⁹⁷⁵ suggests that the act of deciding can create a strong cognitive barrier to treating a
¹⁹⁷⁶ series of decisions as if they were one. However, as elaborated below, the success
¹⁹⁷⁷ of the outcome distribution for overcoming this cognitive barrier in the current
¹⁹⁷⁸ paradigm is a novel and important finding.

¹⁹⁷⁹ This chapter found that some choice bracketing facilitated risk aggregation in
¹⁹⁸⁰ description-based repeated-play gambles. This paradigm has never been a target of
¹⁹⁸¹ research. Early work on risk aggregation involved multi-play gambles, which treated
¹⁹⁸² gambles as simultaneous and identical. However, most risky choice outside the lab
¹⁹⁸³ involves considering multiple choices independently, as in repeated-play paradigms.
¹⁹⁸⁴ Most repeated-play paradigms have involved providing participants with feedback,
¹⁹⁸⁵ or allowing them to sample from outcome distributions. Large real-life investments
¹⁹⁸⁶ are different, as their outcomes are not eventuated immediately (and do not allow
¹⁹⁸⁷ for distribution sampling). The limited prior work using description-based repeated-
¹⁹⁸⁸ play gambles did not consider the effect of choice bracketing on risk aggregation.
¹⁹⁸⁹ As such, the paradigm used in this chapter allowed for the investigation of choice
¹⁹⁹⁰ bracketing in a way that is more isomorphic with real-life prescriptions.

¹⁹⁹¹ Experiment 1 found evidence for the effects of similarity, presentation, and
¹⁹⁹² awareness of the number of projects. Experiment 2 found evidence for the effect of
¹⁹⁹³ an outcome distribution but did not replicate the presentation and awareness effects.

2. Effect of choice bracketing on risk aggregation

1994 Subsequent follow up experiments (reported in Appendices A.3 and A.4) again
1995 tested the similarity and awareness effects. These experiments found evidence for
1996 naive diversification (an advantage for low similarity) when considering all projects
1997 once and did not replicate the trial-by-trial interaction from Experiment 1.

1998 Therefore, in addition to the novelty of the paradigm itself, this chapter found
1999 that choice bracketing facilitates risk aggregation, if aided by the aggregated
2000 distribution. As per Hypothesis 2.5, Experiment 2 found that showing a distribution
2001 of outcome probabilities without inter-trial feedback reduced risk aversion. Further,
2002 there was mixed evidence for Hypothesis 2.3, such that people were less risk averse
2003 when the set of projects they saw were dissimilar, but only when offered them as a
2004 portfolio (see Appendix A.3). There was only minimal evidence for Hypotheses 2.1
2005 and 2.2, suggesting that viewing projects together and an awareness of the number
2006 of projects are not sufficient to encourage aggregation. Altogether, it seems that
2007 subtle contextual cues are often not sufficient to encourage risk aggregation and
2008 that people need risk to be aggregated for them explicitly in order to understand
2009 the benefits of aggregation.

2010 2.4.1 Theoretical implications

2011 The finding that participants are less risk averse when provided with an
2012 aggregated outcome distribution is congruent with previous work (e.g., Redelmeier
2013 & Tversky, 1992). However, when distributions have been previously used, gambles
2014 were identical—as in multi-play paradigms—and used immediate feedback for
2015 repeated-play paradigms (e.g., Benartzi & Thaler, 1999). As mentioned previously,
2016 both these paradigms have limited ecological validity because usually people are
2017 faced with non-identical sequential choices and do not receive immediate feedback.
2018 This work is the first to provide evidence for this aggregation effect with non-
2019 identical gambles without feedback.

2020 The other choice bracketing findings that showed little success with aiding
2021 aggregation are less congruent with previous research. Sokol-Hessner et al. (2009)
2022 and Sokol-Hessner et al. (2012) found that encouraging participants to make decisions

2. Effect of choice bracketing on risk aggregation

akin to a professional investor increased the amount of risky choices they made. The results showed that a subtler manipulation—whether or not participants were aware of the number of choices to be made—is not sufficient to encourage aggregation. Hsee et al. (1999) found that useful, but hard-to-interpret, attributes were used more when the options were presented jointly, rather than separately. In the case of these experiments, the “hard to interpret” element of the decision set was the risk of the projects. Contrary to Hsee et al. (1999), it seems that risk was not always accounted for more when projects were presented jointly, rather than separately. More study is needed to understand whether the effects that were seen in Experiment 1 but not replicated in the subsequent experiments are due to statistical chance or specific elements of the experiment.

Research on the effect of option similarity on choice (e.g., Markman & Medin, 1995) suggests that alignable differences are more important than non-alignable differences. Further, the effects of multi-play gambles and outcome distributions on risk aggregation are only seen when participants perceive the options as fungible (e.g., DeKay & Kim, 2005). As such, it was predicted that a set of investments that involve the same type of investment would be seen as more similar, and therefore be considered as fungible. Hypothesis 2.3 predicted that this would facilitate a broad bracketing, and therefore more risk aggregation.

Instead, the results showed that choice similarity did not affect individual project allocations. However, when participants were given an all-or-nothing choice for the entire set of projects, those that viewed dissimilar projects were more likely to take the entire set projects than those that viewed similar projects. This is different from the initial hypothesis, however, it may still suggest an effect of choice bracketing. That is, this effect was only found when participants were asked about the entire portfolio of projects, rather than when they had a chance to make a choice about each project. The way that the question was framed may have acted to broadly bracket the choices by forcing the choice.

A diversified portfolio is one whose investments are uncorrelated or negatively correlated. According to Portfolio Theory (Markowitz, 1952), a diversified portfolio

2. Effect of choice bracketing on risk aggregation

2053 is preferred to one that is not diversified, because it reduces the probability of a loss.
2054 When some investments have losses, others will have gains—the root of “don’t keep
2055 all your eggs in one basket.” Typically, questions of gamble aggregation assume
2056 that each gamble is independent. That is, the gambles are uncorrelated. As such,
2057 aggregation of a portfolio already assumes that the portfolio is somewhat diversified
2058 (or at least that the gambles aren’t perfectly correlated).

2059 In the case of the similarity effect, the choice bracketing did not seem to
2060 encourage aggregation, but instead appears to have encouraged a naive diversification
2061 (Heddesstrom et al., 2006; Read & Loewenstein, 1995). It could not have been
2062 actual diversification, because the projects did not contain correlational information.
2063 Instead, participants could have been more eager to accept the project portfolio
2064 due to the higher variability between projects (due to the similarity manipulation).

2065 2.4.1.1 How does choice bracketing facilitate aggregation?

2066 Much of the literature (e.g., Benartzi & Thaler, 1999) is not clear about why
2067 choice bracketing occurs. Some explain the effect of bracketing on aggregation
2068 using risk aversion (e.g., Read et al., 1999), while others refer to the increased
2069 weighting of potential losses (Webb & Shu, 2017).

2070 Decision-from-experience *sampling* studies explain the underweighting of rare
2071 events (as opposed to the overweighting that occurs with decisions-from-description)
2072 by sampling bias and recency effects (e.g., Hertwig et al., 2004; Wulff et al., 2018).
2073 That is, they explain that people are less risk averse for positive EV gambles because
2074 when they sample from the distribution they only sample a small amount (usually
2075 approximately 20 times) so they do not experience rare events very often. Also,
2076 the latter half of the sequence of sampling is significantly more predictive than the
2077 former (recency effect). Some decision-from-experience *feedback* studies explain this
2078 effect by “choice inertia” (Camilleri & Newell, 2011). That is, “the tendency to
2079 repeat the last choice, irrespective of the obtained outcome” (p. 383). However,
2080 there is not much more elaboration beyond this. Repeated-play gambles show more
2081 underweighting than multi-play gambles. This is said to be due to a “reliance

2. Effect of choice bracketing on risk aggregation

2082 on a very small set of samples” (Camilleri & Newell, 2013, p. 64). However, this
2083 explanation does not account for repeated-play effects independently.

2084 The experiments in this chapter shed some light about the mechanisms behind
2085 why choice bracketing may affect risk aggregation in repeated-play gambles without
2086 feedback. Two explanations were proposed: participants may realise that some
2087 gains will offset the losses, or they may need explicit aggregation. Not finding
2088 evidence for the subtle choice bracketing manipulations suggests that people do
2089 not intuitively consider that the gains of their choices may offset the potential
2090 losses. Perhaps the possibility of recouped losses would become more salient when
2091 other participants are explicitly told of this possibility, as in Sokol-Hessner et al.
2092 (2009). Their explicit instruction manipulation is introduced above as appearing
2093 unrealistically strong, but the results of this chapter suggest that people do need
2094 very explicit scaffolding in order to use risk aggregation.

2095 2.4.2 Practical implications

2096 This research implies some prescriptions for capital allocation decision-making.
2097 For instance, even if managers implement processes that encourage a joint evaluation
2098 of projects, this may be insufficient to encourage aggregation. Projects need to very
2099 explicitly be considered as individual components in a portfolio in order to facilitate
2100 better risk aggregation. Some companies are already implementing processes that
2101 make this more explicit (Lovallo et al., 2020). This is especially important for those
2102 that would still have to evaluate projects separately. Further, this work shows the
2103 importance of being explicit about the forecasted probabilities of project success.
2104 Doing this is necessary for the aggregation process. Even more ideal would be to
2105 forecast project success using an entire probability distribution for the different
2106 possible outcomes. However, research shows that people struggle to construct such
2107 distributions (e.g., Alpert & Raiffa, 1982; Schaefer & Borcherding, 1973; Tversky &
2108 Kahneman, 1974; von Holstein, 1971) and Chapter 4 shows that people struggle to
2109 use such variance information when making allocation decisions. Regardless, the
2110 benefits of risk aggregation can be used even if forecast information is limited (e.g.,

2. Effect of choice bracketing on risk aggregation

2111 only a point estimate and a probability) and only one project is being considered.
2112 Specifically, a proposed project can be seen in a larger context by aggregating
2113 it with projects from the immediate past.

2114 Interestingly, participants were less risk averse about a portfolio of projects
2115 when industries differed, compared to when they were all from the same industry.
2116 Simply manipulating the similarity of financially-irrelevant semantics of a set of
2117 choices affected participants' risk aversion. This has implications for managerial
2118 settings. Executives in multi-business firms often have to make capital allocation
2119 decisions that involve comparing dissimilar projects. How can an oil well exploration
2120 project be appropriately compared to an oil refinery? Or to a microchip project?
2121 Chapter 4 suggests that evaluating dissimilar business projects is more difficult to
2122 comparing similar projects. The current work suggests that managers may actually
2123 be *less* likely to realise the benefits of aggregation when they are in a less diversified
2124 company. As such, managers should complement an understanding of aggregation
2125 with that of diversification. This might help to avoid being biased by a lack of
2126 variety of projects despite a potentially high level of diversification.

2127 2.4.3 Future research

2128 The main novelty of the experiments in this chapter comes from increasing
2129 ecological validity of risky choice problems by removing inter-trial feedback. Future
2130 work should test even more realistic scenarios. Such studies should involve managers,
2131 ideally in multi-business firms. Investigating whether the choice bracketing findings
2132 from these experiments replicates in a sample of managers will help to determine
2133 whether these results could be applied to real-world managerial decision-making.
2134 This is especially important since Haigh and List (2005) found that professional
2135 traders show more myopic loss aversion than students. Further, the similarity,
2136 awareness, and presentation manipulations should be tested with managers since it
2137 is possible that they have a greater sense of naive aggregation and are therefore
2138 more likely to be more amenable to such manipulations. The addition of extra
2139 payment for better performance on the task might also assist in making the task

2. Effect of choice bracketing on risk aggregation

more isomorphic with real-world managerial decisions. Further, in the present experiments, participants viewed the projects all in the space of one session. However, this is not completely isomorphic to real life, where managers make many other decisions that are unrelated to the large risky investments at their companies. Future research should test participants over a longer period of time (as in Beshears et al., 2016) in order to see whether the effects of the manipulations replicate in a more realistic environment.

2. Effect of choice bracketing on risk aggregation

2343

Joint evaluation of multiple projects

2344 Chapter 2 found that people struggle to aggregate risk even when provided
2345 with choice bracketing cues that could have built on an intuitive sense of how
2346 aggregation reduces risk. The finding that people are more likely to accept many
2347 gambles at once (e.g., Samuelson, 1963; Wedell & Bockenholt, 1994), even without
2348 any aids to calculate risk, suggests that people can gain an intuition for the benefits
2349 of aggregation. Yet, in the current work, people instead considered projects one
2350 at a time and only leveraged the benefits of aggregation when given an explicit
2351 visualisation of what it entails.

2352 This shows that it is important to change organisational policy to encourage
2353 considering business projects jointly. Doing this means that the risk can be
2354 concurrently aggregated. In real-life capital allocation scenarios, when managers
2355 evaluate projects sequentially, an aggregated distribution can also be presented
2356 using any number of projects that were considered in the recent past. This
2357 means that a strategy of project risk aggregation can be implemented at any
2358 stage in an organisation's lifespan. Relatively new ventures can implement these
2359 recommendations by waiting until a certain number of project proposals have
2360 been accrued before aggregating.

3. Joint evaluation of multiple projects

2361 Considering projects jointly is also useful for accountability purposes. The usual
2362 incentive structure in organisations that judges each project outcome independently
2363 is likely to punish risk-taking due to its potential negative consequences and not
2364 due to the information that was available at the time of evaluation. Framing
2365 a set of projects as a portfolio means that any subsequent success or failure of
2366 one project can be traced back to the entire batch, and the performance of the
2367 whole portfolio can be evaluated.

2368 Business projects might not always be either accepted or rejected, as in Chap-
2369 ter 2. Instead, top-level managers might ask for project proposals from lower-level
2370 managers, and then allocate funds from the available budget. An organisation
2371 might also have a initial “culling” phase, and a subsequent ranking phase. When
2372 initially considering a set of projects, some might be rejected according to certain
2373 rules. For instance, an NPV might not meet a certain minimum cut-off. The
2374 remaining projects in the set can then be ranked in order of priority and receive
2375 an allocation of capital from the budget.

2376 A few potential problems arise at the point that projects are considered jointly
2377 for ranking and allocation. For instance, it might not be easy to compare between
2378 the projects in the set. As discussed in Chapter 1, diversification of business
2379 units has become very popular in large organisations. Therefore, most hierarchical
2380 organisations are likely to face difficult comparisons when deciding on how to
2381 rank and allocate capital to projects that originated in different divisions. A non-
2382 hierarchical organisation that develops one type of product may be able to simply
2383 compare across any number of intrinsic project attributes, whereas a diversified
2384 organisation is likely to have to rely on more abstract financial metrics, such as NPV.
2385 Such metrics are “abstract” because they can be applied in almost any domain.

2386 For instance, when comparing across two oil well projects, there can be both
2387 attributes intrinsic to the project, such as the amount of hydrocarbons that are
2388 extracted per hour, and also the more abstract financial metrics. There is a potential
2389 interaction between the ease that managers have to compare across the projects and
2390 the kinds of measures that are used to make the comparison. Two similar projects,

3. Joint evaluation of multiple projects

such as two oil wells can be evaluated using litres of hydrocarbons extracted per hour, whereas an oil refinery cannot. In the case that two dissimilar projects are compared, managers can use financial metrics to compare across domains. This can lead to comparable accuracy as long as the abstract metrics are as reliable as the intrinsic project features.

A concern that arises out of a reliance on such metrics is that underlying variance is not taken into account. Forecast estimates such as NPV rely on many assumptions and contain much inherent uncertainty, so managers that use them should be cautious about over-relying on them. Chapter 4 tested people's sensitivity to forecast estimate variance information. That is, will people use NPV more when the variance information suggests that it is a reliable measure, than when the information suggests that it is unreliable?

Chapter 2 manipulated project presentation and found no significant difference between when projects were considered jointly or separately. This was explained by the bounds on people's ability to intuitively aggregate. However, it was unclear what components of the projects people focused on both because they were not explicitly manipulated and because the task involved a binary choice (accept or reject). A relative allocation measure for multiple projects with systematically varied attributes would allow to determine the influence of those different attributes. Therefore, Chapter 4 considered the situation in which people are already presented with choices together and asked to evaluate the projects by allocating a hypothetical budget.

Further, Chapter 4 identified the factors that affect people's decisions independently from the potential risk of losing hypothetical money, which is a large reason for the effects in the previous chapter. Risk aversion was accounted for by making it clear that no losses are possible. This was achieved by using only positive NPVs, which implies that the project is not forecasted to lose money.

Chapter 4 also manipulated how easy the project attributes are to compare in order to identify the ways that decision-making in a diversified organisation might be different to that of a more integrated organisation. Chapter 2 manipulated similarity by either showing a set of projects from the same industry or a set from

3. Joint evaluation of multiple projects

2421 different industries. This was meant to simulate an integrated and diversified firm,
2422 respectively. This manipulation was not as strong because there were no project
2423 attributes that could be aligned or not. That is, there was nothing actually non-
2424 alignable. This may explain the equivocal similarity effect. Chapter 4 more fully
2425 manipulated alignability by having project attributes be critical to the evaluation.
2426 These project features were shown explicitly so that the difficulty of the comparison
2427 is more obvious.

It is not possible to compare apples and oranges. But it is possible to compare apples and oranges in terms of some specific attribute—to say that apples deliver twice as many calories per dollar or that oranges deliver twice as many vitamin C units per dollar.

—Robinson (1944, p. 13)

2450

2451

2452 4.1 Introduction

2453 One of the most important tasks that executives face is allocating capital within
2454 their company. This requires ranking different projects based on their importance

4. Project similarity bias and variance neglect in forecast metric evaluation

and predicted success, and allocating limited capital respectively (not unlike a scientific funding agency). Ranking projects requires comparing them across a number of dimensions. For example, an executive in an oil company might have multiple proposals on his or her desk for where to explore for oil next and how to do so. Figuring out what makes one oil discovery project better than another one is relatively easy. However, consider a different scenario in which the executive has to allocate capital between an oil discovery project and an oil refinery project. The dimensions of an oil refinery project that distinguishes good from bad projects may be totally different from the dimensions of oil discovery projects that do the same. Think of a funding agency giving out fellowships and deciding between two cognitive scientists, or a cognitive scientist and a physicist. What makes a physics proposal better for the field of physics than a cognitive science proposal is for cognitive science?

Structure-mapping theory (SMT; Gentner, 1983; Gentner & Markman, 1997) provides a model of comparison that psychologically distinguishes these two kinds of allocation tasks. SMT models comparison as a process of bringing conceptual structures into alignment which, when possible, puts shared component dimensions into correspondence. Alignment both highlights when two conceptual structures share dimensions, and also highlights how the two structures differ along those shared dimensions, called *alignable differences*. For example, when comparing two oil discovery projects, all the relevant processes of planning an exploration and measuring the amount of hydrocarbons in a prospect might be identical, but the specific amount measured will be different. This is the alignable difference: a difference between the two projects that is constrained within the same conceptual structure. However, when comparing between an oil field and a refinery, there will be significantly more *non-alignable differences*, because the two domains do not share component dimensions. That is, many of the processes that exist in the exploration business unit have a significantly different dimensional structure to those in the refinery business unit, such that it will be difficult to find meaningful alignments. More non-alignable differences mean that there are less opportunities to make meaningful comparisons, and so would make predicting project success and

4. Project similarity bias and variance neglect in forecast metric evaluation

2485 ranking their priority more difficult. This chapter experimentally examined project
2486 comparisons and how such comparisons affect capital allocation decisions. The
2487 working hypothesis was that comparisons with more alignable differences will make
2488 project predictions more precise, and project rankings easier and more informative,
2489 than a comparison with non-alignable differences.

2490 However, what happens when the two domains are too disparate for a decision-
2491 maker to align them, but the task demands that they be aligned? This is actually
2492 a bit of uncharted territory experimentally. The prediction is that when forced to,
2493 people will grab at any piece of information that they can and then try to infer
2494 and abstract as much as seems reasonable to ease the alignment. This is in fact
2495 what occurs very frequently in business settings. Corporate enterprises continue to
2496 embrace diversification strategies in their investments, and so constantly have to
2497 make capital allocation choices that involve very disparate domains. To overcome
2498 these difficult comparisons, executives rely on various financial measures that in
2499 theory can apply to any project or business proposal. These financial measures work
2500 well to ease the burden of the difficult comparison by abstracting away from the
2501 complexities of the individual projects, and just focus on financial information such
2502 as total costs, projected profits, etc. Initially hard-to-compare projects can therefore
2503 be more easily evaluated by comparing values on individual numerical measures.

2504 The most common financial measure that is used by executives in order to value
2505 business project proposals is Net Present Value (NPV; Graham & Harvey, 2001;
2506 Graham et al., 2015; Remer et al., 1993). NPV is the difference between the money
2507 that a project is forecasted to make and the initial investment in its development
2508 (accounting for the time value of money), as seen in Equation (1.1).

2509 NPV is commonly used to decide about capital allocation and investment. The
2510 simple rule is that if a project's NPV is positive, then it is financially viable, and
2511 if NPV is negative, then it is not. However, the use of NPV has been criticised,
2512 both by academics and practitioners (Fox, 2008; Willigers et al., 2017). The main
2513 criticism is that there is underlying variance within the NPV measure that is not
2514 made apparent by the final form of the measure, a single numerical value. For

4. Project similarity bias and variance neglect in forecast metric evaluation

2515 instance, NPV is dependent on the cash inflows that are projected for each year
2516 of the project. However, financial forecasting is known to often be inaccurate
2517 and prone to optimism bias (Lovallo & Kahneman, 2003; Puri & Robinson, 2007).
2518 Therefore, there is bound to be variation in the reliability of NPV measures as
2519 a function of the forecasting error in the cash flow calculations. The duration of
2520 the project and the discount rate are further sources of variance that are hidden
2521 by the single numerical value of NPV.

2522 As such, the secondary goal of this research was to investigate the extent to
2523 which people are sensitive to variance information (from financial forecasting) when
2524 making capital allocation decisions. This consideration is especially important
2525 in the capital allocation situations illustrated above, in which executives need to
2526 compare between projects from disparate domains and therefore have to rely on
2527 NPV. This matters because the NPV calculated from different domains may have
2528 different underlying forecasting error, which may compromise the utility of using
2529 NPV as the basis of the comparison. Do executives sufficiently account for the
2530 inherent variance in the measure that they rely on so much? Research shows that
2531 people are good at extracting variance information when experiencing numerical
2532 sequences (Rosenbaum et al., 2020). However, people struggle to use variance
2533 information when it is represented numerically (Batteux et al., 2020; Galesic &
2534 Garcia-Retamero, 2010; Konold et al., 1993; Vivaldi & Coville, 2021).

2535 4.1.1 Experiment summary

2536 Experiment 1 investigated the effect of alignment on the decision-making of
2537 naive participants' capital allocation to a set of fictional projects. NPV reliability
2538 was manipulated by directly stating whether it is a reliable measure because
2539 the naive participants were assumed not to have the requisite knowledge to be
2540 sensitive to reliability information otherwise. This experiment predicted that when
2541 projects are alignable, participants use NPV if they are told that it is a reliable
2542 measure, but do not use it if they are told that it is unreliable. However, when

4. Project similarity bias and variance neglect in forecast metric evaluation

2543 projects are not alignable, participants were predicted to use NPV regardless
2544 of the stated NPV reliable.

2545 Experiment 2 investigated the decision-making of management students in
2546 almost the same situation as Experiment 1. The main difference was that instead of
2547 telling participants the reliability of NPV, this experiment manipulated the level of
2548 associated *numerical* NPV reliability. That is, the width of numerical ranges around
2549 an NPV. Participants were predicted to rely more on NPV in the non-alignable
2550 projects than in the alignable projects. However, this experiment predicted that
2551 there will be no effect of numerical reliability, since there is very little evidence that
2552 people are sensitive to variance information when represented numerically.

2553 Experiment 3 again tested the alignment and reliability effects in a non-business
2554 population, but manipulated both verbal and numerical reliability in the same
2555 experiment to allow for direct comparisons. An effect of reliability was predicted in
2556 the verbal reliability condition, but not in the numerical reliability condition. Fur-
2557 ther, this experiment used project descriptions with clearer profitability indicators,
2558 and added a larger selection of business industries.

2559 4.2 Experiment 1

2560 Experiment 1 investigated the effects of alignment and explicit NPV reliability
2561 information on capital allocation decisions. The structural alignment literature
2562 suggests that people weigh alignable differences more heavily than non-alignable
2563 differences. It was expected that people would use NPV more than any other
2564 product attributes (because it applied to every product). However, this effect
2565 should vary with participants' perceived reliability of the value. That is, if other
2566 project dimensions were alignable, then it should be easier to adjust the use of
2567 NPV based on its reliability. However, it was predicted that in low alignment there
2568 will be a reliance on NPV, as the sole alignable difference, regardless of its stated
2569 reliability. These effects were measured by considering the linear trend of how
2570 NPV, across projects, relates to the money allocated to the projects. Critically,

4. Project similarity bias and variance neglect in forecast metric evaluation

2571 participants saw both NPV and other features intrinsic to each project domain, and
2572 these were inversely related. Therefore, a positive NPV amount trend indicated
2573 a reliance on NPV, whereas a negative trend indicated a reliance on the intrinsic
2574 project features. First, Experiment 1 tested the following omnibus hypothesis:

2575 **Hypothesis 4.1—Overall effect.** The alignment \times reliability amount \times NPV
2576 amount interaction will be significant.

2577 Initially, the specific effects were tested excluding the no NPV condition.
2578 Comparing across dissimilar projects will be difficult, so participants are expected
2579 to rely on NPV more in such a scenario than when they have other alignable
2580 attributes. Therefore, Experiment 1 tested the following:

2581 **Hypothesis 4.2—Alignment effect.** The linear NPV amount trend will be
2582 higher, on average, in low alignment than in high alignment.

2583 Participants are likely to moderate their allocations based on the provided
2584 reliability information. However, it is more likely that they will do this when
2585 they have multiple options for metrics to use than when only NPV is alignable.
2586 Therefore, Experiment 1 tested the following:

2587 **Hypothesis 4.3—Moderation of NPV reliability by alignment.** The NPV
2588 amount \times reliability interaction will be stronger in the high alignment than in low
2589 alignment.

2590 More specifically, it is expected that when projects are similar, participants will
2591 rely on NPV more (positive NPV amount trend) when they are told that it is reliable
2592 and rely more on the projects' intrinsic features (negative NPV amount trend) when
2593 they are told that it is unreliable. However, when projects are dissimilar, it is
2594 expected that participants will rely solely on NPV solely, regardless of what they
2595 are told about its reliability. Therefore, Experiment 1 tested the following:

2596 **Hypothesis 4.4—NPV reliability in high alignment.** In high alignment, the
2597 linear NPV amount trend will be higher in the high reliability condition than in
2598 the low reliability condition

4. Project similarity bias and variance neglect in forecast metric evaluation

2599 **Hypothesis 4.5—NPV reliability in low alignment.** In low alignment, the
2600 linear NPV amount trend will not differ significantly between reliability conditions

2601 A no NPV condition was used to gain a better understanding of the baseline
2602 responding to the materials without NPV. This was used to determine the extent
2603 of participants' reliance on NPV. When projects were similar, this condition
2604 was expected to be equivalent to the low reliability condition, as participants
2605 disregard NPV. When projects were dissimilar, this condition was expected to
2606 express the average participant value judgements for the project descriptions, which
2607 should result in a more or less flat NPV amount trend. Therefore, Experiment 1
2608 tested the following:

2609 **Hypothesis 4.6—No NPV comparison in high alignment.** In high alignment,
2610 the linear NPV amount trend will be higher in the high reliability condition than
2611 in the no NPV reliability condition.

2612 **Hypothesis 4.7—No NPV comparison in low alignment.** In low alignment,
2613 the linear NPV amount trend in both the low and high reliability conditions will be
2614 higher than the no NPV reliability condition.

2615 4.2.1 Method

2616 4.2.1.1 Participants

2617 One hundred and eighteen people (55 female) were recruited from the online
2618 recruitment platform Prolific. Participants were compensated at a rate of £5 an
2619 hour. The average age was 29.42 ($SD = 9.25$, $min = 18$, $max = 73$). Table 4.1 shows
2620 the between-subjects condition allocation. NPV amount was varied within subjects.

2621 4.2.1.2 Materials

2622 **4.2.1.2.1 Instructions** The instructions page explained to the participants,
2623 who did not necessarily have business experience, about the task and NPV. However,
2624 this page was also used to manipulate whether participants were told that NPV
2625 was reliable or unreliable as a financial measure. Participants in the low NPV

4. Project similarity bias and variance neglect in forecast metric evaluation

Table 4.1: Experiment 1 group allocation.

Alignment	Reliability amount	N
High	High	26
High	Low	17
High	No NPV	17
Low	High	21
Low	Low	16
Low	No NPV	21
Total	-	118

2626 reliability condition were told that NPV is an unreliable metric, whereas those in
 2627 the high NPV reliability condition were told that NPV is a reliable metric. Those in
 2628 the no NPV condition saw instructions that did not include the NPV explanation.
 2629 Critically, participants were told to invest in products with a high objective value
 2630 (because a better quality product is not always better in a consumer goods market).
 2631 Since participants might still not use this instruction when directly viewing the
 2632 projects, Experiment 3 used projects with attributes that more inherently conveyed
 2633 quality. Appendix B.1.1.1.1 shows the instructions used in Experiment 1.

2634 **4.2.1.2.2 Project display** Participants read sets of fictional business projects
 2635 for which to potentially allocate capital. The high alignment display was a table
 2636 that listed various attributes for five projects (see Figure 4.1). The low alignment
 2637 display presented each project as individual paragraphs that described the relevant
 2638 attributes with full sentences (see Figure 4.2). In the high alignment display, all
 2639 projects were of the same product type and the concrete attributes were consistent.
 2640 In the low alignment display, each project was of a different product with concrete
 2641 attributes relevant to that project. For both alignment conditions, each project
 2642 description included an NPV.

2643 This alignment manipulation was reinforced by visual presentation. The
 2644 table format was better afforded by the high alignment condition because all
 2645 the dimensions were shared. However, this confounded alignment with presentation

4. Project similarity bias and variance neglect in forecast metric evaluation

	Project 1	Project 2	Project 3	Project 4	Project 5
Product	Laptop	Laptop	Laptop	Laptop	Laptop
RAM (GB)	4	8	32	2	16
Hard drive (GB)	500	750	2000	250	1000

Processor (Ghz)	2.4	3.2	3.8	1.6	3.6
NPV (\$)	663	495	70	887	252

Figure 4.1: An example of a high alignment display in Experiment 1.

2646 style. This was addressed in Experiment 3 by equating the table format across
 2647 both alignment conditions.

2648 Critically, the value of the concrete attributes were always in conflict with
 2649 the NPV. For instance, Project 4 always had the lowest value for each of the
 2650 concrete attributes for laptops, but always had the highest NPV. This meant that
 2651 participants' allocations could be used as a proxy measure for an individual's
 2652 degree of dependence on NPV.

2653 **4.2.1.2.3 Allocation** Participants completed a capital allocation task (see
 2654 Figure 4.3), adapted from Bardolet et al. (2011), in which they were asked to
 2655 allocate a hypothetical yearly budget across the given five projects.

2656 **4.2.1.2.4 Additional measures** Other measures were included apart from
 2657 allocation. The stimuli and analyses for these measures are reported in Appen-
 2658 dices B.1.1.1 and B.1.2, respectively. Specifically, participants were asked to
 2659 forecast the future returns of the projects (see Figure B.4), rank the projects
 2660 (see Figure B.5), indicate their confidence in their decisions (see Figure B.6), and
 2661 justify their decisions (see Figure B.7).

4. Project similarity bias and variance neglect in forecast metric evaluation

PROJECT 1

This project is about developing a new shampoo. It will have a 400 mL capacity, and the patented Dandruff Reduction Factor was 17 at testing. The fragrance was optimally effective for 3 metres, and the Safety Authority gave it a 81% safety rating. The NPV is estimated to be \$685.

PROJECT 2

This project is about developing a new laundry machine. The machine will have a 12-star energy rating and an 8L capacity. The maximum speed rate is 900 rpm and it will have six different cycle programs. The NPV is estimated to be \$500.

PROJECT 3

This project is about developing a new mountain bike. It will have a tensile strength of 910 megapascals, and a suspension for travel of 200mm. It will have a 12-speed cassette and is guaranteed for at least three tours. The NPV is estimated to be \$81.

PROJECT 4

This project is about developing a new laptop computer. It will have 2GB of RAM and a hard drive with 250GB capacity. The resolution will be 768px, and the processor speed will be 1.6 Ghz. The NPV is estimated to be \$894.

PROJECT 5

This project is about developing a new backpack. It will have eight separate compartments for different types of storage, and a total capacity of 30L. The company will offer a four-year warranty, and the material is an 800-denier nylon fabric. The NPV is estimated to be \$251.

Figure 4.2: An example of a low alignment display in Experiment 1. Border added for clarity.

4. Project similarity bias and variance neglect in forecast metric evaluation

How will you allocate your budget across these five projects (percentages must sum to 100%)?

	0	10	20	30	40	50	60	70	80	90	100
PROJECT 1	<input type="text"/>										0
PROJECT 2	<input type="text"/>										0
PROJECT 3	<input type="text"/>										0
PROJECT 4	<input type="text"/>										0
PROJECT 5	<input type="text"/>										0
Total:											0

Figure 4.3: The allocation task. Border added for clarity.

4.2.1.3 Procedure

After reading the relevant instruction page, participants completed the forecasting task directly after each project display in the low alignment condition. For the high alignment condition this was done directly under all projects. Participants then ranked the projects and subsequently answered the allocation, confidence, and justification questions.

4.2.2 Results

A mixed factorial ANOVA was conducted to investigate the effects of alignment and NPV reliability on participants' allocations. As seen in Figure 4.4, the alignment \times reliability amount \times NPV amount interaction was significant, $F(6.57, 367.76) = 2.18$, $p = .039$, $\hat{\eta}_p^2 = .038$. The analyses excluding the no NPV condition showed the expected results. The NPV amount trend was higher in the low alignment condition than in the high alignment condition, $M = 61.70$, 95% CI [33.02, 90.37], $t(76) = 4.29$, $p < .001$, averaging over reliability amount. This shows that people relied on NPV more when projects were dissimilar than when they were similar.

Further, the NPV amount \times reliability amount interaction was stronger in the high alignment condition than in the low alignment condition, $M = 67.81$, 95% CI [10.47, 125.16], $t(76) = 2.36$, $p = .021$. Specifically, in high alignment, the NPV

4. Project similarity bias and variance neglect in forecast metric evaluation

amount trend was higher in the high reliability condition than in the low reliability condition, $M = -63.47$, 95% CI $[-100.00, -26.94]$, $t(112) = -3.44$, $p = .001$, whereas in low alignment, there was no significant difference between reliability conditions, $M = 4.35$, 95% CI $[-34.52, 43.21]$, $t(112) = 0.22$, $p = .825$. This shows that people only used the reliability information to moderate their allocations when projects were similar and not when they were dissimilar.

The comparison with the no NPV condition revealed the expected pattern. In high alignment, the linear NPV trend was only significantly lower in the no NPV condition than the high reliability condition, $M = 75.70$, 95% CI $[39.17, 112.24]$, $t(112) = 4.11$, $p < .001$, and not the low reliability condition, $M = 12.24$, 95% CI $[-27.94, 52.41]$, $t(112) = 0.60$, $p = .547$. However, in low alignment, the linear NPV trend was significantly lower in the no NPV condition than both the low reliability condition, $M = 64.63$, 95% CI $[25.76, 103.50]$, $t(112) = 3.29$, $p = .001$, and the high reliability condition, $M = 60.29$, 95% CI $[24.14, 96.43]$, $t(112) = 3.30$, $p = .001$.

The ranking, confidence, and forecast mean data were all largely congruent with the allocation findings (see Appendix B.1.2). The results also showed that forecasts of those in the low alignment condition had higher standard deviations than those in the high alignment condition (see Appendix B.1.2.4). However, this did not replicate in subsequent experiments (see Appendices B.5.2.2 and B.6.2.2).

4.2.3 Discussion

Experiment 1 found evidence for the effect of alignment on laypeople's decision-making in capital allocation scenarios. Specifically, when projects were comparable, people used NPV when they were told that it was reliable, but not when they were told that it was unreliable. However, they used NPV regardless of reliability when it was the only shared dimension across products.

Experiment 1 manipulated *verbal* NPV reliability. That is, participants were explicitly told whether NPV was considered to be a reliable metric or not. However, in the real-world the reliability of a metric is more commonly expressed in numerical form, such as a range around an estimate. Experiment 2 attempted to replicate the

4. Project similarity bias and variance neglect in forecast metric evaluation

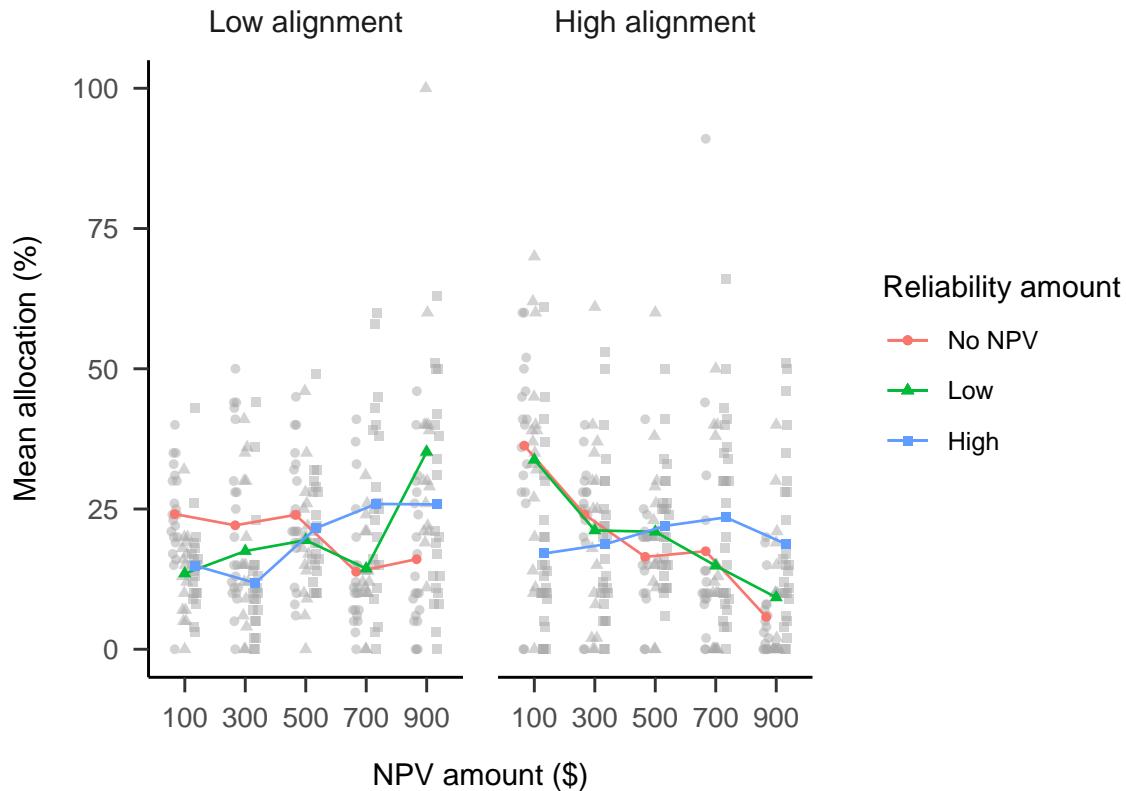

Figure 4.4: Mean allocation across NPV amount, by alignment and reliability amount conditions. In mixed factorial designs, error bars cannot be used to make inferences by “eye” across all conditions. Therefore, error bars are not included. Raw data are plotted in the background. When interpreting this figure, consider the linear trends in NPV amount.

alignment effects, while manipulating the *numerical* NPV reliability associated with each project, rather than the verbal reliability as used in Experiment 1. Further, people with sufficient experience with financial theory and analysis might be able to successfully draw inferences from such information. Therefore, Experiment 2 used a sample of Masters of Management students, instead of the laypeople used in Experiment 1.

4.3 Experiment 2

Experiment 2 investigated the effects of alignment and numerically-expressed variance information on capital allocation decisions. In Experiment 1 the information about the variance inherent in the NPVs was communicated explicitly as the conclusion (e.g., “NPV is unreliable”). In Experiment 2, however, only the actual

4. Project similarity bias and variance neglect in forecast metric evaluation

2720 variance information itself was communicated without the conclusion about its
2721 reliability. Specifically, participants saw the range of predicted values (akin to a
2722 confidence interval). Therefore, while Experiment 1 manipulated *verbal* reliability,
2723 Experiment 2 manipulated *numerical* reliability. Further, Experiment 2 studied
2724 participants with more business experience than the previously used laypeople
2725 samples. This experiment tested whether the previous findings of an alignment
2726 effect will replicate with people with more business experience. The experiment
2727 also tested whether this population is sensitive to variance in forecasts.

2728 Hypothesis 4.2 was again tested to investigate the alignment effect in the new
2729 sample. However, the other hypotheses from Experiment 1 were not tested again
2730 because Experiment 2 manipulated numerical reliability and did not include a
2731 no NPV condition. Research has shown that people are poor at reasoning with
2732 numerical variance information (Batteux et al., 2020; Galesic & Garcia-Retamero,
2733 2010; Konold et al., 1993; Vivaldi & Coville, 2021). Therefore, Experiment 2
2734 tested the following:

2735 **Hypothesis 4.8—No effect of numerical reliability.** The NPV amount ×
2736 reliability amount interaction will not be significant in either alignment condition.

2737 Experiment 2 also investigated the potential to quickly change participants'
2738 understanding, if they did not initially use numerical reliability for their allocations.
2739 Therefore, participants were presented with a short lecture on the importance of
2740 paying attention to variance in financial decision-making. However, results were incon-
2741 clusive, so see Appendix B.2 for a more detailed discussion. Further, Experiment 2
2742 investigated whether participants would be over-confident in their understanding
2743 of NPV (as in Long et al., 2018). These results are also reported in Appendix B.2
2744 as they were not sufficiently relevant to this chapter.

2745 4.3.1 Method

2746 4.3.1.1 Participants

2747 Fifty-four people (28 female) were recruited from a Masters of Management
2748 course at an Australian university. Age information was not recorded. Both the

4. Project similarity bias and variance neglect in forecast metric evaluation

2749 reliability amount conditions (low and high) and alignment conditions (low and
2750 high) were presented within subjects and the order of their presentation was
2751 counterbalanced.

2752 **4.3.1.2 Materials**

2753 **4.3.1.2.1 Instructions** Participants were shown similar instructions to Exper-
2754 iment 1 (see Section 4.2.1.2.1). However, here they were given more information
2755 about NPV (about the discount rate and initial investment). The appendix shows
2756 the full instructions (see Figure B.12).

2757 **4.3.1.2.2 NPV test** Participants were presented with a short and simple test
2758 of their understanding of NPV (see Appendix B.2.1.1.2).

2759 **4.3.1.2.3 Project display** As seen in Figures 4.5 and 4.6, the project display
2760 was as in Experiment 1, except for the addition of another set of projects that differed
2761 in semantic content. That is, the projects were about different types of products (to
2762 allow for a within-subjects manipulation). Along with the single NPV, participants
2763 saw the forecasted ranges of cash flow that were used to calculate the NPV. In the
2764 low numerical reliability condition, the ranges were $\pm 85\%$ around the mean (e.g.,
2765 \$150-\$1850 if the forecast mean was \$1000); whereas in the high numerical reliability
2766 condition, the ranges were $\pm 5\%$ around the mean (e.g., \$950-\$1050 if the forecast
2767 mean was \$1000). Wide ranges should indicate low reliability in the measure, while
2768 narrow ranges should indicate high reliability. Between the four displays, participants
2769 were told to treat each new set of projects as independent to the other sets.

2770 **4.3.1.2.4 NPV knowledge ratings** Participants were asked to rate the con-
2771 fidence of their knowledge of NPV at multiple points in the experiment. The
2772 appendix shows an example of this display (see Figure B.15).

4. Project similarity bias and variance neglect in forecast metric evaluation

PROJECT 1

This project is about developing a new pair of wireless earphones. They will have a frequency response of 16-40,000Hz and a sensitivity of 90 db/mW. The battery life is 8 hours and the pair will isolate noise up to 35 dB. The range of the cash inflow for the first year is \$861-\$10,619. The NPV is \$227.27.

PROJECT 2

This project is about developing a new wrist watch. It will be water resistant up to 50m and will have one extra timing feature. The hardness of the glass face is rated 4 on the Moh scale and the strap is 10% leather. The range of the cash inflow for the first year is \$966-\$11,914. The NPV is \$881.82.

PROJECT 3

This project is about developing a new treadmill. It will 12 training programs for different interests and abilities and 10 speed levels. It will also have two small compartments for storage and three adjustable inclination levels. The range of the cash inflow for the first year is \$832.50-\$10,267.50. The NPV is \$81.82.

PROJECT 4

This project is about developing a new couch. It will have a guarantee for 10 years and a lightfastness level of 5. The cover's ability to resist abrasion has been tested to handle 50,000 cycles and it has a softness rating of 70%. The range of the cash inflow for the first year is \$906-\$11,174. The NPV is \$490.91.

PROJECT 5

This project is about developing a new bottle of perfume. It will have a 100 mL capacity, and the scent will be able to last for 12 hours. The fragrance concentration will be 30%, and there will be two layers of notes to the scent. The range of the cash inflow for the first year is \$925.50-\$11,414.50. The NPV is \$654.55.

NPV (\$)	\$636.36	\$490.91	\$18.18	\$872.73	\$300.00

Figure 4.6: An example of a high alignment high reliability display in Experiment 2.

2773 **4.3.1.2.5 Variance lecture** Participants were shown a short lecture on the
 2774 importance of paying attention to variance information, in an attempt to facilitate a
 2775 subsequent increased use of the numerical reliability information in their allocations
 2776 (see Appendix B.2.1.1.4 for more details and the lecture slides).

2777 **4.3.1.3 Procedure**

2778 Participants saw the instructions and NPV explanation, and completed a
 2779 simple test to demonstrate their understanding of NPV. They then completed four
 2780 counterbalanced capital allocation trials (equivalent to each condition combination),
 2781 and subsequently saw a brief presentation about the importance of paying attention
 2782 to variance in financial decision-making. Participants then completed a further two
 2783 capital allocation trials of two of the trials that they saw earlier. They were shown
 2784 the allocation values that they provided earlier, and were given the opportunity
 2785 to change them. Participants rated their knowledge of NPV once before the NPV
 2786 test, re-rated after the test, and again after the four project displays. They were

4. Project similarity bias and variance neglect in forecast metric evaluation

2787 then asked to rate their knowledge of NPV as they believe it had been both before
2788 and after the variance presentation.

2789 4.3.2 Results

2790 A within-subjects factorial ANOVA was conducted to investigate the effects of
2791 NPV amount, alignment, and numerical NPV reliability on participants' project
2792 allocations. Figure 4.7 shows these data. The alignment \times reliability amount \times
2793 NPV amount interaction was significant, $F(2.81, 148.75) = 3.95, p = .011, \hat{\eta}_p^2 = .069$.
2794 However, this appeared to be driven by the difference between alignment conditions
2795 in the interaction between the quadratic NPV amount trend and reliability amount,
2796 $\Delta M = -42.28, 95\% \text{ CI } [-76.96, -7.59], t(53) = -3.14, p = .011$, even after
2797 applying a Šidák correction. The same interaction but with the linear NPV trend
2798 was not significant, $\Delta M = -6.13, 95\% \text{ CI } [-31.50, 19.25], t(53) = -0.62, p = .954$.
2799 Further, the linear NPV trend did not differ between reliability amount condition
2800 in neither the low alignment condition, $\Delta M = -3.19, 95\% \text{ CI } [-18.77, 12.40]$,
2801 $t(53) = -0.41, p = .683$, nor the high alignment condition, $\Delta M = 2.94, 95\%$
2802 $\text{CI } [-12.63, 18.52], t(53) = 0.38, p = .706$. However, averaging over reliability
2803 amount, the linear NPV trend was higher in the low alignment condition than in
2804 the high alignment condition, $\Delta M = 28.19, 95\% \text{ CI } [5.57, 50.81], t(53) = 2.50$,
2805 $p = .016$. This suggests that participants relied more on NPV when projects were
2806 dissimilar than when they were similar.

2807 The ranking data were congruent with these results, while the confidence data
2808 were less so. Further, the NPV knowledge data did not replicate the effect from
2809 Long et al. (2018, Study 1). These analyses are reported in Appendix B.2.2.

2810 4.3.3 Discussion

2811 Experiment 2 replicated the alignment effect found in Experiment 1 with
2812 participants with real-world business experience. That is, Hypothesis 4.2 was
2813 supported, as people relied more on NPV when faced with a set of dissimilar
2814 projects than when projects were all from the same domain. Experiment 2 also

4. Project similarity bias and variance neglect in forecast metric evaluation

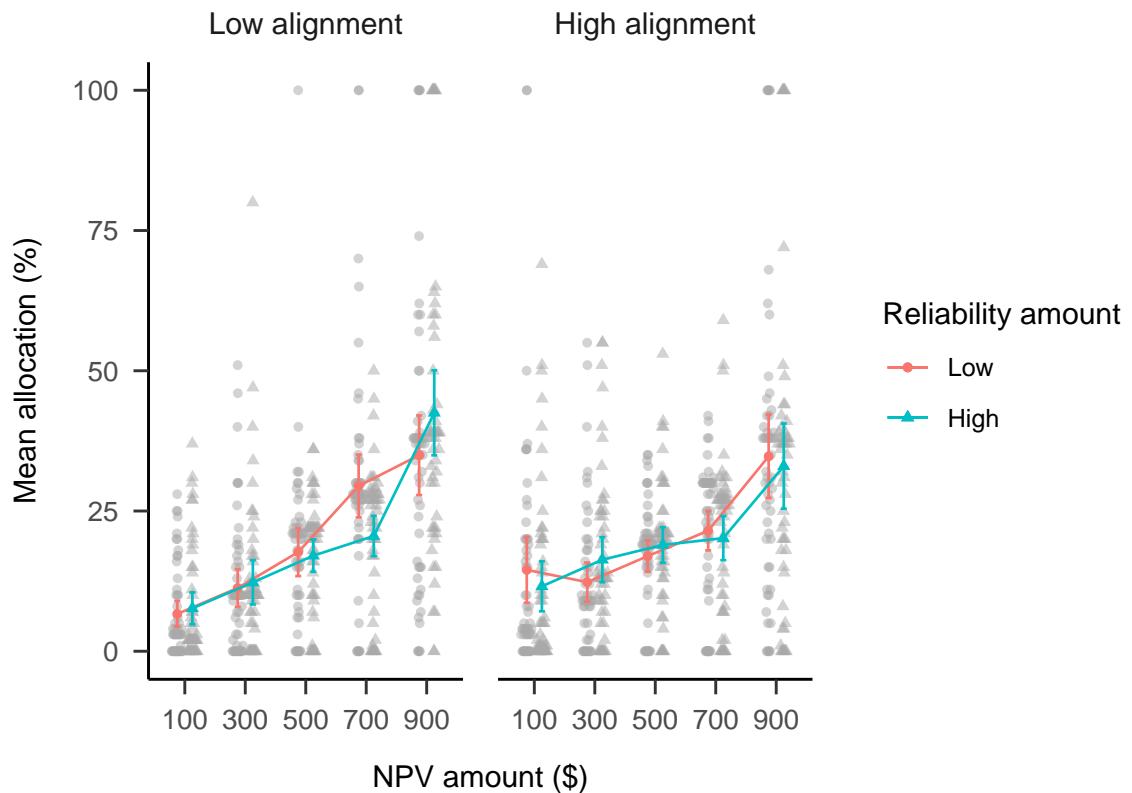

Figure 4.7: Mean allocation across NPV amount, by alignment and reliability amount conditions. Error bars represent 95% confidence intervals, calculated from the within-subjects SEs using the method from Cousineau and O'Brien (2014). Raw data are plotted in the background.

2815 found evidence for Hypothesis 4.8, with no significant differences between the
 2816 numerical reliability amount conditions. While Experiment 2 did not replicate
 2817 the interaction found in Experiment 1, it should be emphasised that these are
 2818 two different effects. In Experiment 1, participants were explicitly told about the
 2819 reliability of the NPV measure, whereas in Experiment 2, they were provided with
 2820 variance information that merely implies NPV reliability. Thus, Experiment 2
 2821 showed that business students are affected by comparability of project sets, but not
 2822 by numerical NPV reliability information. Specifically, participants appeared to
 2823 only focus on the NPV itself, and not on any variations in the underlying noisiness
 2824 of the measure for a specific project.

2825 The participants in Experiment 2 seemed to rely on NPV more than those in
 2826 Experiment 1. This was seen by the steeper linear trends in Experiment 2. This
 2827 discrepancy may be due to the difference in domain experience and exposure to

4. Project similarity bias and variance neglect in forecast metric evaluation

2828 financial metrics in formal study. However, the extra explanation and testing of
2829 NPV for the management students may have also increased its salience. In sum,
2830 the Experiment 2 sample showed clearer trends of NPV reliance, but importantly
2831 was still affected by similarity even when it was manipulated within-subjects.

2832 Experiment 1 tested NPV reliability expressed verbally, while Experiment 2
2833 tested NPV reliability expressed numerically. However, the difference in findings
2834 was confounded by the different populations that were sampled. Further, in both
2835 experiments, the business projects consisted of a limited number of domains. It
2836 is unclear to what extent these specific domains influenced the results. These
2837 projects were centred around consumer products, which were originally chosen to
2838 be more easily accessible to participants without business experience. However,
2839 with these projects, individual features do not necessarily indicate a project's
2840 profitability. For instance, a laptop with a low capacity can be more profitable
2841 than a laptop with a high capacity due to the existence of consumer goods markets.
2842 Experiment 3 addressed these limitations.

2843 Another limitation of the last two experiments was the potential presentation
2844 style confound. The two alignment conditions differed in the number of alignable
2845 differences, but also in the way that the information was presented. The information
2846 in the low alignment condition was presented in paragraphs, whereas the information
2847 in the high alignment condition was presented in tables. While it is likely that
2848 each of these data types would be presented in this way in a business setting, it is
2849 important to rule out that this manipulation did not also unnecessarily increase
2850 task difficulty. Therefore, Experiment 3 attempted to replicate this effect, while
2851 controlling for presentation style.

2852 4.4 Experiment 3

2853 Experiment 3 investigated the effects of alignment, reliability type, NPV amount,
2854 and reliability amount on allocations. Experiment 1 manipulated reliability amount
2855 by using *verbal* prompts. That is, participants were told explicitly whether or

4. Project similarity bias and variance neglect in forecast metric evaluation

not NPV was reliable for a certain project industry. Experiment 2 investigated whether people were able to extract this same kind of reliability information from numerical prompts. That is, participants saw NPVs with either wide or narrow ranges, indicating either low or high reliability of the metric, respectively. However, Experiment 1 sampled laypeople, whereas Experiment 2 sampled a Masters of Management course. Therefore, it was not possible to compare the two reliability types (verbal and numerical) without ruling out the potential confound of population type. As such, Experiment 3 manipulated NPV amount, alignment, and reliability amount, but also added a reliability type factor. Further, presentation style was a possible confound in the alignment manipulation of the previous experiments. That is, the business projects in the high alignment condition were always displayed as a part of a table, whereas the projects in the low alignment condition were displayed in prose, as paragraphs. Experiment 3 fixed this by using the same presentation style across alignment condition.

The expected pattern of results in the verbal reliability condition of Experiment 3 was a replication of Experiment 1. For the numerical reliability condition, findings from a pilot experiment (detailed in Appendix B.8) were used for predictions. This experiment found no significant differences in a similar numerical reliability condition to the one used in Experiment 3. This was therefore expected also for the present numerical reliability condition. The appendix shows a simulation of these hypothesised effects (see Figure B.33). Therefore, as well as again testing Hypotheses 4.1, 4.2, 4.3, 4.4, and 4.5 for the verbal reliability condition, Experiment 3 tested the following:

Hypothesis 4.9—Overall effect. The alignment \times reliability amount \times reliability type \times NPV amount interaction will be significant, such that the effects hypothesised above will be seen in the verbal reliability condition, but none of these effects will be seen in the numerical reliability condition.

4. Project similarity bias and variance neglect in forecast metric evaluation

Table 4.2: Experiment 3 group allocation.

Alignment	Reliability type	N
High	Explicit	112
High	Implicit	112
Low	Explicit	112
Low	Implicit	112
Total	-	448

2883 4.4.1 Method

2884 4.4.1.1 Participants

2885 Four hundred and forty-eight people (176 female) were recruited from the
2886 online recruitment platform Prolific. Participants were compensated at a rate
2887 of £5 an hour. The average age was 41.65 ($SD = 10.3$, $min = 29$, $max = 78$).
2888 Participants reported an average of 6.94 ($SD = 8.23$, $min = 0$, $max = 43$) years
2889 of work in a business setting, and an average of 3.73 ($SD = 6.27$, $min = 0$, max
2890 = 45) years of business education. The mean completion time was 11.35 ($SD =$
2891 10.79, $min = 1.92$, $max = 183.7$) minutes. Table 4.2 shows the between-subjects
2892 condition allocation. The two reliability amount conditions (low and high) were
2893 presented within subjects and the order of their presentation was randomised. As
2894 before, NPV amount was varied within subjects. Therefore, each participant saw
2895 two separate project displays. Appendix B.3.1.1.1 describes the power analysis
2896 conducted to arrive at the sample size.

2897 4.4.1.2 Materials

2898 **4.4.1.2.1 Instructions** Participants saw similar instructions to the previous
2899 experiments, with an added explanation of the NPV reliability information for each
2900 reliability type condition (see Appendix B.3.1.2.1). Further, they completed a test
2901 of basic NPV understanding. This test functioned also as an attention check as,
2902 although it was required to answer, the response should only be one of two letters.

4. Project similarity bias and variance neglect in forecast metric evaluation

2903 **4.4.1.2.2 Project display** The project displays were similar to the previous
2904 experiments. Here, however, participants saw the same presentation style in both
2905 alignment conditions. Each display had a table describing the projects in the set,
2906 with ranking and allocation inputs. The project details were presented as dot
2907 points within the relevant cells of the table. Figure 4.8 shows an example of a
2908 low alignment, low verbal reliability display; and Figure 4.9 shows an example of
2909 a high alignment, high numerical reliability display.

2910 Three elements were counterbalanced: 1. the association of reliability amount
2911 and project set (two variations), 2. the association of business name with NPV
2912 (five latin square variations), and 3. project variation (five variations per alignment
2913 condition). For high alignment, project variation meant the project type. For low
2914 alignment, this meant the intrinsic feature variant for the relevant project type.
2915 Table column order and project display order were both randomised.

2916 **4.4.1.2.3 Interstitial** Before each project display, participants saw an “inter-
2917 stitial” page, whose role was to 1. introduce the next display, and 2. check the
2918 participant’s attention (not required to answer, so can be skipped if the interstitial
2919 text isn’t read). See Figure B.37 in the appendix for an example.

2920 4.4.2 Results

2921 A mixed factorial ANOVA was conducted to investigate the effects of NPV
2922 amount, alignment, NPV reliability amount, and NPV reliability type on partic-
2923 ipants’ project allocations. Figure 4.10 shows these data. Only the main results
2924 are reported here, while the rest of the hypothesised allocation effects are reported
2925 in Appendix B.3.2.1. The predicted four-way interaction (alignment \times reliability
2926 amount \times NPV amount \times reliability type) was not significant, $F(3.20, 1, 420.19) =$
2927 0.71, $p = .555$, $\hat{\eta}_p^2 = .002$. Regardless, the primary hypotheses were supported, but
2928 realised in a different overall pattern than predicted, elaborated below.

4. Project similarity bias and variance neglect in forecast metric evaluation

Carefully read through the project descriptions below and then do the following: 1. Rank the projects between 1 (highest) and 5 (lowest) in order of investment priority in the relevant "Project Ranking" row input; and 2. Allocate each project a percentage (a number between 0 and 100) of the total budget in the relevant "Project Allocation" row input.

Figure 4.9: An example of a high alignment, high numerical reliability display in Experiment3.

2929 **4.4.2.1 Verbal reliability**

2930 The three-way interaction ($\text{alignment} \times \text{reliability amount} \times \text{NPV amount}$)
 2931 in the verbal reliability condition was not significant, $\Delta M = 13.42$, 95% CI
 2932 $[-1.27, 28.11]$, $t(444) = 1.80$, $p = .073$. This is because NPV reliability interacted
 2933 with NPV amount in both alignment conditions. This is a different pattern from
 2934 Experiment 1 where there was no effect of NPV reliability in the low alignment con-
 2935 dition. In high alignment, the interaction between the linear NPV amount trend and
 2936 NPV reliability amount was significant, $\Delta M = -36.63$, 95% CI $[-47.02, -26.25]$,
 2937 $t(444) = -6.93$, $p < .001$. Specifically, the trend was stronger in the high reliability

4. Project similarity bias and variance neglect in forecast metric evaluation

amount condition, $\Delta M = 27.26$, 95% CI [17.69, 36.83], $t(444) = 5.60$, $p < .001$, than in the low reliability amount condition, $\Delta M = -9.38$, 95% CI [-18.86, 0.11], $t(444) = -1.94$, $p = .053$. This shows that, as in Experiment 1, participants moderate their allocations based on verbally-expressed NPV reliability. In low alignment, there was also an interaction between the linear NPV amount trend and NPV reliability amount was significant in low alignment, $\Delta M = -23.21$, 95% CI [-33.60, -12.83], $t(444) = -4.39$, $p < .001$. This suggests that participants were also able to moderate their allocations based on verbal reliability in the low alignment condition.

However, another aspect of the data suggests a greater use of NPV in the low alignment condition. The linear NPV amount trend was stronger in the low alignment condition than in the high alignment condition when averaging over reliability amount, $\Delta M = 28.97$, 95% CI [17.68, 40.26], $t(444) = 5.04$, $p < .001$. This suggests that when NPV reliability was expressed verbally, as in Experiment 1, participants relied more on NPV when projects were dissimilar than when they were similar.

Overall, participants used NPV less when it was described as less reliable in both high and low alignment conditions, and further, used NPV more when projects were less alignable regardless of how reliable NPV was described to be.

4.4.2.2 Numerical reliability

The numerical reliability data were analysed differently to the verbal reliability data because of the different hypothesised effects. The two effects of interest here were the alignment and reliability effects. In the numerical reliability condition, it was hypothesised that the linear NPV amount trend would be equivalent between those in the low and high alignment conditions, averaging over reliability amount. However, this effect was not significant, $\Delta M = 15.19$, 95% CI [3.90, 26.48], $t(444) = 2.64$, $p = .996$. In fact, a post-hoc comparison suggests that the low alignment trend was stronger (with Bonferroni adjustment), $\Delta M = 15.19$, 95% CI [0.78, 29.60], $t(444) = 2.64$, $p = .034$. This is the same pattern as in the

4. Project similarity bias and variance neglect in forecast metric evaluation

verbal reliability condition above and in Experiment 2. Further, the linear NPV trend was not significantly different between reliability amount conditions in both the low alignment condition, $\Delta M = 1.64$, 95% CI [-11.61, 14.90], $t(444) = 0.31$, $p > .999$, and high alignment condition, $\Delta M = -1.21$, 95% CI [-14.46, 12.05], $t(444) = -0.23$, $p > .999$. This shows that participants did not use numerical reliability to moderate their allocations.

Similar to the verbal reliability condition, the use of NPV was stronger in the low alignment condition than it was in the high alignment condition. However, unlike the verbal reliability condition, participants did not moderate their use of NPV based on numerical reliability in either the low or the high alignment condition. In the verbal reliability condition, they moderated their choices in both alignment conditions.

4.4.3 Discussion

Hypotheses 4.1, 4.2, 4.3, and 4.4 were supported in the verbal reliability condition. This shows that, while overall participants prefer to use NPV as a proxy for project quality in their allocations, they still use verbal reliability information. Specifically, when projects are similar, people use NPV when they are told that it is reliable, and use alternative metrics more so when told that it is not reliable. However, Experiment 3 did not find evidence for Hypothesis 4.5. Instead, Experiment 3 found that even in the low alignment condition, participants still moderated their use of NPV. They still used NPV regardless of reliability condition, shown by the positive NPV amount trend in both reliability conditions. However, Experiment 3 shows that participants used NPV less when told that it was unreliable.

Further, Experiment 3 did not find support for Hypothesis 4.9 mostly likely because of the unexpected effects of NPV amount in the numerical reliability condition. The hypothesis was constructed in response to the results of a pilot study (documented in Appendix B.8) that replicated the results of Experiment 1 in the verbal reliability condition, but did not replicate the results of Experiment 2 in the numerical reliability condition. That is, when faced with numerical ranges as variance information, people did not seem to even use the midpoint in their

4. Project similarity bias and variance neglect in forecast metric evaluation

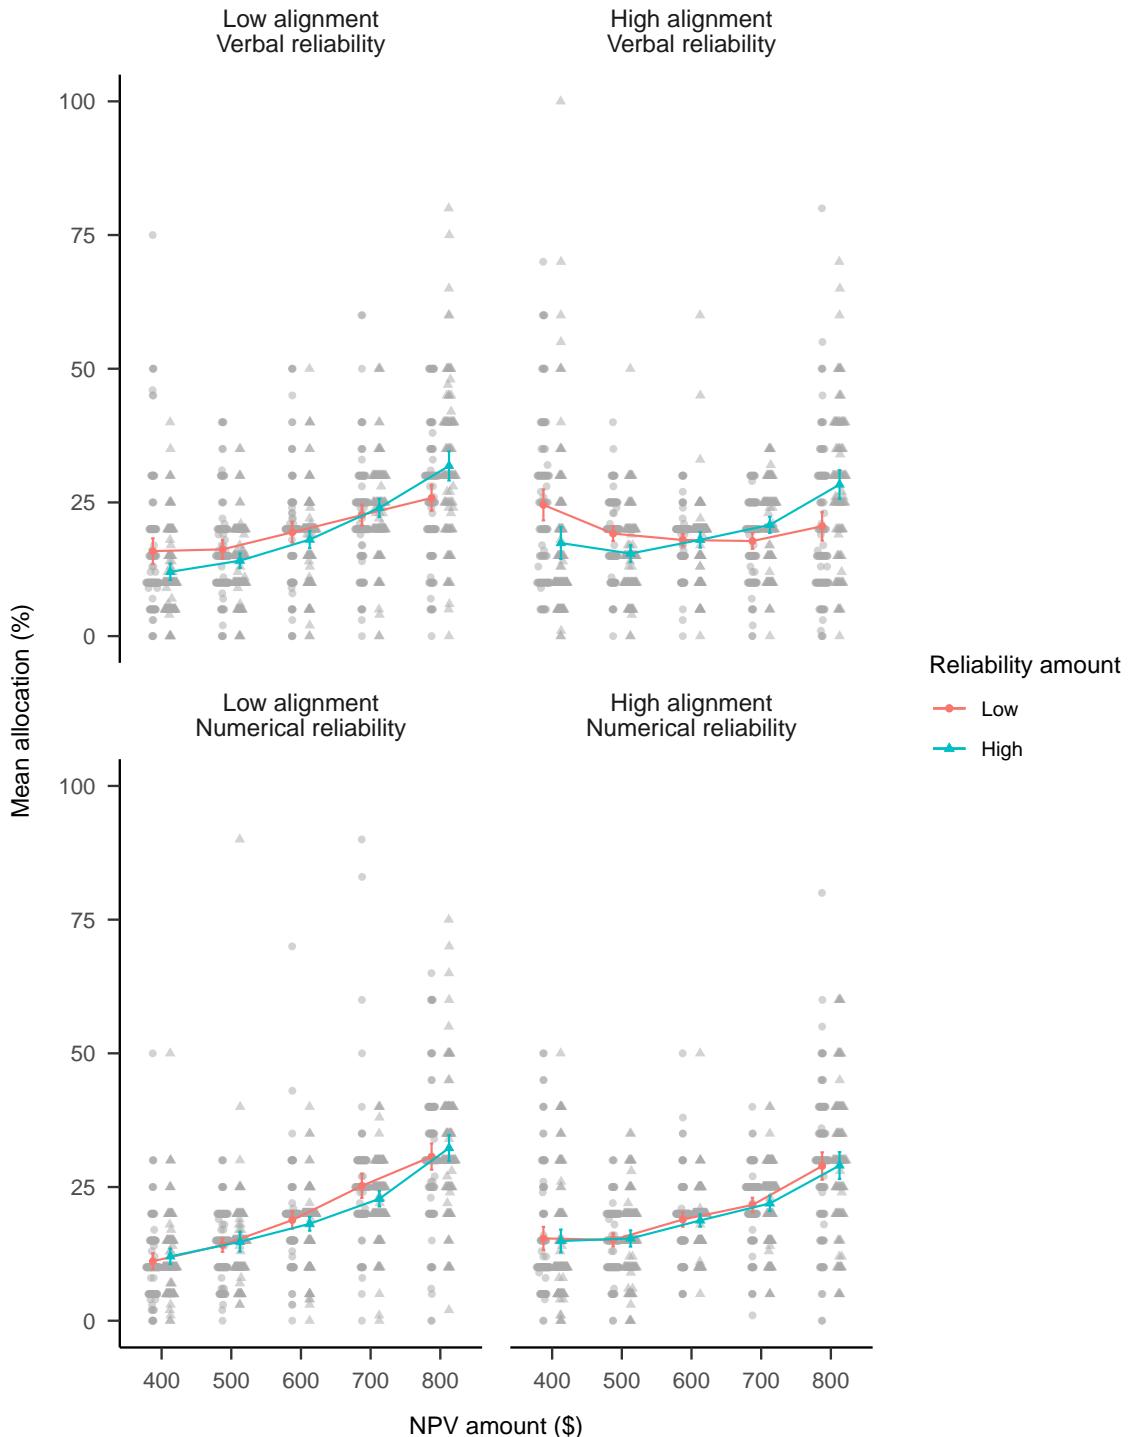

Figure 4.10: Mean allocation across NPV amount, by alignment, reliability amount, and reliability type conditions. Error bars represent 95% confidence intervals, calculated from the within-subjects SEs using the method from Cousineau and O'Brien (2014). Raw data are plotted in the background.

4. Project similarity bias and variance neglect in forecast metric evaluation

2996 decisions. Experiment 3, on the other hand, replicated the finding of Experiment 2
2997 in the numerical reliability condition. Specifically, people used NPV more when
2998 projects were dissimilar, but critically, they did not use numerical range information
2999 to moderate their allocations.

3000 **4.5 General discussion**

3001 Across three experiments there were two main findings: 1. NPV is used more
3002 when options are hard to compare in the low alignment conditions; and 2. people
3003 do not consider numerical variance information, despite this being important to the
3004 reliability of the NPV forecasts. This pattern with numerical reliability information
3005 contrasted with the frequent use of verbal indicators of reliability. This numerical
3006 variance neglect is surprising, since other work showed that people can readily
3007 extract variance information when experiencing numerical sequences (Rosenbaum
3008 et al., 2020). Both the verbal and numerical effects were consistent across both naive
3009 and experienced populations, which indicates their persistence. People make use
3010 of metrics with alignable differences when in a situation that requires comparison
3011 across disparate options. However, they do not sufficiently moderate their use of
3012 such metrics even when they have alternative attributes to use.

3013 Experiment 1 found that when participants were told that NPV was unreliable,
3014 they did not use it in their allocation decisions, but when they were told that it was
3015 reliable they did. Experiment 2 found that people with some business experience
3016 relied on NPV more for capital allocation when the rest of the information was
3017 non-alignable, compared to when it was alignable. However, participants did not
3018 take into account the numerical reliability information when making these decisions.
3019 Experiment 3 found further evidence of these effects, within one experimental design.

3020 Alignable differences have been shown to be important to decision making in
3021 many settings (Markman & Loewenstein, 2010; Markman & Medin, 1995). The
3022 experiments in this chapter are novel in the investigation of alignment effects in
3023 a capital allocation paradigm. Further, these experiments considered the extent

4. Project similarity bias and variance neglect in forecast metric evaluation

3024 to which the reliability of an alignable measure (NPV) affects the way people
3025 use it. The experiments found that this is dependent on the availability of other
3026 alignable differences in the choice set. If other alignable differences are available,
3027 then participants are willing to reduce their use of a supposedly unreliable alignable
3028 measure (and use it when told that it is reliable). However, when no other alignable
3029 differences are available, then the unreliable, but alignable, measure is used less.
3030 This was found in both Experiment 1 and 3, as well as to lesser extent in a pilot
3031 study (reported in Appendix [B.4](#)).

3032 Financial measures such as NPV are useful because of their alignability. That
3033 is, they act as an alignable difference regardless of the inherent similarity of a
3034 set of projects. Psychologically, these measures are useful because they allow
3035 for relevant inferences (Lassaline, [1996](#)) and because they offer an abstraction of
3036 concrete details (Doumas & Hummel, [2013](#)). However, the theoretical account of
3037 structural alignment does not directly speak to the real-world implications when
3038 there is a need for non-alignable comparisons. NPV is a type of abstraction that
3039 allows comparison between different aspects of a company. For instance, comparing
3040 an oil field project with a refinery project might be made easier by using NPV. On
3041 the other hand, this increased alignment might actually hide important information
3042 because it does not consider the finer complexities inherent within each business
3043 unit. The forecasts used to calculate NPV are based on different indicators in each
3044 business unit, and there are likely to be differences in variance between each unit's
3045 estimates. As such, one can imagine a continuum of similarity comparisons in which
3046 usefulness of comparison increases with the level of alignability, but is moderated
3047 by the level of abstraction that is required to achieve the alignment.

3048 The finding that people, even with some business experience, do not sufficiently
3049 consider variance information is surprising, but understandable. It is surprising
3050 because so much of financial decision making depends on considering different sources
3051 of variance (e.g., risk, volatility, and uncertainty). However, it is understandable
3052 because research from psychology and statistics education shows that statistics
3053 students and people in general have a poor ability to draw statistical inferences (e.g.,

4. Project similarity bias and variance neglect in forecast metric evaluation

3054 Galesic & Garcia-Retamero, 2010; Konold et al., 1993). Future research should
3055 investigate the conditions under which people's sensitivity to variance information
3056 can be facilitated. For instance, it is unclear whether it is merely salience that is
3057 lacking, and that therefore visual aids could be useful, or whether further explicit
3058 explanation of the statistical inference is necessary. Pilot experiments suggest that
3059 participants still struggle to use numerical reliability information, even when given
3060 very explicit instructions (see Appendix B.7).

3061 A possible limitation of these experiments is the use of NPV as the only financial
3062 metric. In the business world there are many metrics that serve similar functions
3063 and would be used as a tool to deal with non-alignable options, as NPV was in the
3064 current study. Therefore, future research should attempt to replicate the current
3065 findings with different financial measures.

3066 Future research should also investigate the boundary conditions of the reliability
3067 effect. That is, people seem to be responding to explicit reliability information, but
3068 not to variance information that implies reliability. Future research should attempt
3069 to identify the minimal kind of information about variance that participants need
3070 in order to understand the relevant implications about reliability. Participants
3071 may simply not notice the variability information, or assume that it irrelevant.
3072 For instance, future research could test participants in a condition in which the
3073 variability information is more salient.

3134

Looking for alignment in past cases

3135 Chapter 4 found that people do not sufficiently weigh the importance of numerical
3136 variance information in capital allocation. This is important for when projects are
3137 dissimilar because people might not pay attention to the differing variance that
3138 underlies NPV across different domains. However, there are also implications for
3139 high alignment scenarios. When projects are alignable this means that managers
3140 are likely to have a choice of using both abstract metrics as well as intrinsic project
3141 features. Managers may use a metric such as NPV, whose variance may suggest a lack
3142 of reliability, despite being able to use intrinsic projects features. They may therefore
3143 miss out on an opportunity to use different, potentially more reliable measures.

3144 An evaluation of a non-alignable set of projects can therefore lead to many
3145 potential pitfalls. Such a situation is likely to occur in most hierarchical organisations
3146 and be more common the more the organisation is diversified. Chapter 3 discussed
3147 that a solution to managers not aggregating the risk of multiple projects is a
3148 concurrent evaluation of projects as a portfolio. However, the solution to the
3149 evaluation of dissimilar project in the case of a diversified organisation is likely
3150 to involve significantly more difficult structural changes in the organisation. For
3151 instance, this may mean divesting certain divisions of the organisation, as GE has
3152 been doing over the last few years (Scott, 2018).

5. Looking for alignment in past cases

3153 Other solutions are also possible. For instance, organisations can develop a more
3154 normative use of metrics and take into account underlying uncertainty. However, this
3155 kind of change might require substantially more statistical reasoning abilities than
3156 can be expected of managers without better decision guidelines. Another solution
3157 managers may use is to look to evidence from similar projects from outside the
3158 organisation. This is useful because a diversified organisation may not have enough
3159 points of reference for a project proposal within it. Doing this both does not require
3160 substantial restructuring of the organisation as in divestment and is already an
3161 on-going practice, as opposed to aiming to facilitate managers' statistical reasoning.

3162 Evidence from similar projects may come in the form of an individual case study
3163 from another organisation, or a research report that describes a statistical result.
3164 Case studies are especially important in managerial decision-making since they are
3165 used extensively in business school teaching materials. Therefore, managers are
3166 likely to look to case studies to inform their decisions. But would they think that a
3167 single case study is more useful than statistical data? The literature on anecdotal
3168 bias suggests that they might. Therefore, Chapter 6 considers the influence of an
3169 anecdote on project allocation when it conflicts with statistical evidence.

3170 Previous work showed that people often do not give evidence appropriate
3171 weighting in their decisions (Griffin & Tversky, 1992). Anecdotal and statistical
3172 evidence are potentially conflicting sources of evidence, so it is important to
3173 appropriately weigh their influence when making a decision. It is possible for
3174 these sources of evidence to conflict because statistical estimates commonly refer
3175 to the mean value of a distribution, whereas individual cases may be sampled, for
3176 instance, from either tail of the distribution. This kind of comparison would give
3177 the appearance of conflicting information, especially if the distribution is skewed.
3178 In the same way that in Chapter 4 the intrinsic project features conflicted with the
3179 abstract financial metric, in Chapter 6 the description of an anecdote conflicted
3180 with the financial metrics of the target project.

3181 Chapter 6 considered how people dealt with such conflicting information. That
3182 is, would they focus on one metric or use a trade-off? In the previous chapter, people

5. Looking for alignment in past cases

3183 did not seem to predominantly use one cue or another. The fact that those in the low
3184 alignment condition relied on NPV more than those in the high alignment condition
3185 means that those in the high alignment condition were still referring to the intrinsic
3186 project features to some extent. Specifically, the different measures' influence may
3187 have been integrated in a form of trade-off. However, there was no clear way of
3188 determining this, because the allocation measure was aggregated in the analysis.
3189 Chapter 6, however, set up the conditions so that it was possible to determine
3190 whether participants were using anecdotes exclusively, partially, or not at all.

We like stories, we like to summarize, and we like to simplify

—Nassim Nicholas Taleb (2007, p. 63)

6. Anecdote similarity moderates anecdotal bias in capital allocation

3216 6.1 Introduction

3217 A good story is often more persuasive than data. While usually harmless in
3218 daily settings, poor judgement due to a bias towards anecdotal evidence can lead
3219 to larger-scale negative consequences. Perhaps the most prominent example of such
3220 an error in judgement is the belief that a vaccine causes a certain disorder based on
3221 isolated stories, despite contradictory scientific evidence. An analogous error exists
3222 in settings such as managerial decision-making. In business, managers use analogies,
3223 usually called *case studies*, as a part of strategic decision-making. Case studies are
3224 examples of previous situations that are considered similar by the decision-maker
3225 and are used to draw inferences about a target problem. When comparing such
3226 examples with aggregated data these are called anecdotes.

3227 Many businesses use case studies to inform their decisions, but often struggle to
3228 use them successfully (Gavetti & Rivkin, 2005). This is likely because of the high
3229 salience of companies that have ended up either very successful or very unsuccessful.
3230 That is, people are often uninterested in average outcomes, but are captivated by
3231 both positive and negative extreme outcomes. Increased salience of an anecdote
3232 may increase its influence above useful statistical data. Further, increased anecdote
3233 salience may also shift attention away from structural similarities in favour of more
3234 surface similarities. Both of these issues may explain unsuccessful use of case studies.

3235 The first consideration when using a case study is its merit relative to available
3236 aggregated statistical data. That is, if the case study is a single data point in a set
3237 of other relevant cases, then using the statistical properties of the larger sample
3238 is more inferentially informative than using a single case from within the sample
3239 (unlike perhaps when the single case is somehow the most relevant example from
3240 the sample). Despite the utility and availability of large sample data, research has
3241 shown that people can prefer anecdotal evidence over statistical data (e.g., Freling
3242 et al., 2020; Jaramillo et al., 2019; Reinard, 1988; Shen et al., 2015).

3243 However, if this larger sample is not available (or is ignored), then the second
3244 consideration when using a case study is the extent of its similarity to the target

6. Anecdote similarity moderates anecdotal bias in capital allocation

problem. Research on the psychology of similarity judgements distinguishes between surface and relational similarity (Gentner, 1983). The consensus of this research is that the more conceptual structures two cases share, the more useful they are in decision-making (Lassaline, 1996; Markman & Medin, 1995). As such, case studies that are similar to a target problem on a merely surface level are less useful than those that are related by shared conceptual structure.

Previous research has considered the role of similarity and analogical reasoning in business-related decision-making (e.g., Gavetti et al., 2005). Other work has investigated the impact of anecdotes in capital allocation decisions, and separately the impact of similarity on anecdotes (summarised below). However, it is unclear to what extent an anecdote's similarity to the target problem will affect the influence of anecdotes in capital allocation decisions. Further, it is unclear whether people will be sensitive to information about the distribution from which the anecdote was sampled.

6.1.1 Anecdotal bias

Anecdotal bias is the finding that anecdotal evidence sometimes influences people's beliefs more than statistical evidence. Journalists, for instance, are well aware of the power of anecdotes. An analysis of approximately 29,000 New York Times editorials showed a reliance on anecdotes to drive arguments (Al Khatib et al., 2017). While some research concluded that statistics are more persuasive than anecdotes (e.g., Allen & Preiss, 1997; Hoeken, 2001; Hornikx, 2005) and others were equivocal (Winterbottom et al., 2008), a number of studies have found evidence for anecdotal bias (e.g., Jaramillo et al., 2019; Ratcliff & Sun, 2020; Reinard, 1988; Reinhart, 2006; Shen et al., 2015). Zebregs et al. (2015) suggested that this disparity in findings might be due to statistics having an effect on beliefs and attitudes, and anecdotes affecting intention. A more recent meta-analysis of 61 studies showed that overall people find statistical evidence more persuasive than anecdotal evidence (Freling et al., 2020). However, even if statistical evidence is overall more persuasive across studies, anecdotes that add no additional information to co-presented statistics still influence judgement (Jaramillo et al., 2019). Further,

6. Anecdote similarity moderates anecdotal bias in capital allocation

3274 the meta-analysis found that people tend to prefer anecdotal evidence over statistical
3275 data when the stakes are more emotional, medical, or relevant to the decision-maker.
3276 In business, the decisions are clearly relevant to the decision-maker.

3277 6.1.2 Anecdotal bias in business

3278 It is important to investigate anecdotal bias in business because of the impli-
3279 cations this might have on managers' use of case studies. There are many cases
3280 of managers successfully using analogies from anecdotal cases, but also of failures
3281 to analyse properly (Gavetti et al., 2005; Gavetti & Rivkin, 2005). There is
3282 very little research on anecdotal bias in business, but the existing work finds clear
3283 evidence of the effect. In fact, the recent meta-analysis by Freling et al. (2020) only
3284 included the work in Wainberg et al. (2013) as one such paper.

3285 Wainberg et al. (2013) gave a sample of managers and other professionals a
3286 choice between two audit firms, which varied in their audit deficiencies for various
3287 clients. The experiment was designed in a way that the statistical evidence favoured
3288 one firm and the anecdotal evidence favoured the other firm. Participants viewed
3289 one of five conditions. In the *anecdote only* condition, they were shown examples of
3290 firm deficiencies; whereas in the *anecdote & statistics* condition, they were shown
3291 the same as in the anecdote condition, but also saw the number of deficiencies
3292 and clients. However, participants were not explicitly provided the proportions for
3293 these values. In the *statistics only* condition, the proportions and clients without
3294 deficiencies were made explicit. The *anecdote & enhanced statistics* condition added
3295 the anecdotes to the statistics only condition. The terminology here is confusing
3296 because nothing about the way the statistics are presented to the participants is
3297 "enhanced" beyond how they are presented in the statistics only condition. However,
3298 the *anecdote & enhanced statistics—judgment orientation* condition emphasised the
3299 importance of proportions and keeping absolute numbers in their relevant context.

3300 Wainberg et al. (2013) found evidence for anecdotal bias. They measured
3301 the proportion of participants choosing the firm favoured by the statistical data.
3302 Those that saw only the anecdote chose this firm equivalently to those that saw

6. Anecdote similarity moderates anecdotal bias in capital allocation

3303 both the anecdote and the statistics. Further, participants chose this firm less
3304 when seeing both types of information than when seeing just statistics, even when
3305 the underlying proportions were made explicit (anecdote & enhanced statistics
3306 condition). This provided evidence of anecdotal bias, as participants ignored
3307 contradictory statistical data.

3308 Finding no difference between the anecdote & statistics condition and the
3309 anecdote only condition implies that the anecdotal bias effect is “complete.” That
3310 is, this shows that the statistics displayed did not play a role in influencing choice.
3311 A “partial” effect would have been one in which the anecdote & statistics condition
3312 had been chosen more than the anecdote only condition. This would mean that
3313 statistics still played some role in influencing choice.

3314 The other important finding in this work was that highlighting relevant statistical
3315 features and providing some explanation of statistical inference reduced the anecdotal
3316 bias. This is important because it suggests that potential psychological biases can
3317 be reduced with a re-framing of the provided information and an explanation of
3318 the relevant statistical concepts.

3319 Wainberg (2018) conducted a similar study to Wainberg et al. (2013), but with
3320 a capital budgeting task, as opposed to a binary choice. Participants had to choose
3321 between purchasing three production-line machines for a mid-sized company that
3322 prints circuit boards. The provided statistical data suggested that Machine A
3323 was better than Machine B, which was better than Machine C. Participants were
3324 either given only this information, or were also provided with an anecdote. This
3325 anecdote was in the form of an email correspondence from a colleague from another
3326 company that recommended against Machine A (the best option). As in Wainberg
3327 et al. (2013), participants were assigned to *anecdote & statistics* and *statistics only*
3328 conditions. In the *judgment orientation I* and *judgment orientation II* conditions,
3329 participants were told to “think like a scientist” and either received an explanation of
3330 what this means, which was either short or a long, respectively. These explanations
3331 emphasised the importance of statistical inference.

6. Anecdote similarity moderates anecdotal bias in capital allocation

3332 Wainberg (2018) found evidence for anecdotal bias. Including a contradictory
3333 anecdote alongside statistical evidence (the anecdote & statistics condition) reduced
3334 the proportion of choosing Machine A. They also found that the addition of
3335 instructions that emphasised scientific thinking reduced this bias. Unlike Wainberg
3336 et al. (2013), Wainberg (2018) could not determine whether this was a complete
3337 or partial anecdotal bias because they did not use an anecdote only condition.
3338 Further, neither work considered the effect of the similarity of the content of the
3339 anecdote to the target problem.

3340 6.1.3 Effect of similarity

3341 The extent of one's reliance on an anecdote should arguably be moderated by
3342 its similarity to the target problem. Previous work has discussed the importance
3343 of weighting previous cases by their similarity to the present situation (Gilboa &
3344 Schmeidler, 1995; Lovallo et al., 2012). For instance, consider a medical treatment
3345 that with contradictory statistical and anecdotal evidence. A large-scale aggregated
3346 study found 99% efficacy of the treatment, while an individual reports on social
3347 media that they became sick as a side-effect of the treatment. On the one hand, an
3348 individual's decision of whether to use the treatment should be informed more by
3349 the aggregated data than by the anecdote. On the other hand, the individual might
3350 have reason to be concerned if the person who became sick was the individual's
3351 identical twin. The inference that the individual may therefore also need to
3352 be cautious about the treatment arises from a specific causal model based on
3353 the two cases' shared genetics.

3354 There have been mixed results regarding the effect of anecdote similarity on
3355 the extent of anecdotal bias. Hoeken and Hustinx (2009, Study 3) found evidence
3356 for an effect of similarity on anecdotal bias with laypeople for a variety of claims.
3357 As well as manipulating whether participants received a claim supported by an
3358 anecdote or statistical evidence, they manipulated whether the anecdotal evidence
3359 was similar or dissimilar to the claim that it was supporting. They found that
3360 similar anecdotes were more persuasive than dissimilar anecdotes. Hoeken (2001)

6. Anecdote similarity moderates anecdotal bias in capital allocation

3361 did not find evidence for an effect of similarity about a local government proposal
3362 with a student sample. Similarly, Hornikx (2018) considered the effect of similarity
3363 on anecdotal bias in local government policy decision-making. The researchers did
3364 not find an effect of similarity, or an effect of anecdotes. However, they measured
3365 persuasiveness and perhaps requiring to make more concrete decisions will be a
3366 better test for a more real-life scenario.

3367 Apart from the need to clarify the effect of similarity on the anecdotal bias
3368 effect, it is important to clarify how such an effect might work. Research on
3369 analogical reasoning has made the distinction between simple surface similarity
3370 and deeper relational similarity (Gentner, 1983). As mentioned above, one's use
3371 of an anecdote should be moderated by the extent to which it is associated by an
3372 underlying causal mechanism or mere surface similarity. Imagine a manager of a
3373 multi-divisional company that is deciding how to allocate capital between an oil
3374 well project and a technology project. Would hearing of a recent failed oil well
3375 project at a different company influence the manager's allocation decision? If so,
3376 would it influence the decision because of the fact that the anecdote and one of
3377 the target projects are from the same industry (surface similarity)? Or would the
3378 manager look to the underlying reason of why the anecdote failed and first identify
3379 if this mechanism is relevant to the target oil project (relational similarity)? The
3380 experiments in this chapter investigate whether the anecdotal bias effect is due to
3381 causal inductive reasoning or merely the association between the valence of the
3382 anecdote and surface similarity with the target.

3383 6.1.4 Experiment summary

3384 Experiment 1 investigated whether anecdotal bias in a capital allocation paradigm
3385 is moderated by similarity of the anecdotes. Further, it tested whether giving extra
3386 information about statistical thinking would encourage participants to consider the
3387 statistics over the anecdote. Experiment 1 used a negative anecdote, which is an
3388 example of an unsuccessful case. This kind of anecdote has been shown to produce
3389 anecdotal bias in both medical (Jaramillo et al., 2019) and business (Wainberg,

6. Anecdote similarity moderates anecdotal bias in capital allocation

3390 2018) decision-making. However, Jaramillo et al. (2019) found less of a bias in
3391 positive anecdotes, which are examples of successful cases, and Wainberg (2018)
3392 did not consider these at all. Therefore, Experiment 2 attempted to replicate the
3393 effect of similarity on anecdotal bias with a positive valence anecdote. Further,
3394 Experiment 2 provided participants with information about the sample distribution
3395 of the anecdote, whereas Experiment 1 did not. This allowed for an informal test
3396 of whether people are sensitive to such information.

3397 6.2 Experiment 1

3398 Experiment 1 investigated the effects of similarity and anecdotal bias on capital
3399 allocation. Participants were asked to allocate a hypothetical budget between two
3400 business projects. They also saw a case study that was either similar or dissimilar
3401 to the target project (but still from the same industry). Further, participants
3402 were allocated to the same conditions as in Wainberg (2018), except that of the
3403 two judgement orientation conditions, only the *judgment orientation II* condition
3404 was used. Further, an anecdote only condition was used. For the conditions with
3405 statistical evidence, participants also saw aggregated information about the success
3406 of similar projects in the form of Net Present Value (NPV) as well as a reliability
3407 measure. One project was clearly better than the other when considering the
3408 statistical data, but the anecdotal evidence suggested the opposite.

3409 Previous research found that people are more persuaded by negative anecdotes
3410 than by positive statistical data in capital allocation scenarios (Wainberg, 2018).
3411 While other work has shown that similar anecdotes are more persuasive than
3412 dissimilar anecdotes (Hoeken & Hustinx, 2009, Study 3), it is unclear how similarity
3413 changes the anecdotal bias effect. As such, the main question was whether anecdotal
3414 bias will be greater when the anecdote is similar than when it is dissimilar. The
3415 target project was supported by the statistics, but is inconsistent with the anecdotes.
3416 Further, Experiment 1 only used negative anecdotes. So, evidence of anecdotal bias

6. Anecdote similarity moderates anecdotal bias in capital allocation

3417 is given when allocation in a statistics only condition is higher than allocation to
3418 an anecdote & statistics condition. Therefore, Experiment 1 tested the following:

3419 **Hypothesis 6.1—Anecdotal bias is moderated by the similarity of negative**
3420 **anecdotes.** Allocations to the target project will be higher when only the statistics
3421 are presented and when the statistics are accompanied by a low similarity anecdote,
3422 in comparison to when the statistics are accompanied by a high similarity anecdote.
3423 In addition, allocations are predicted to not be affected by the low similarity
3424 anecdote at all. That is, the statistics only condition should not differ from the low
3425 similarity anecdote & statistics condition.

3426 Experiment 1 predicted that that the anecdotal bias effect will be complete, as
3427 in Wainberg et al. (2013). Specifically, the participants presented with the high
3428 similarity anecdote along with the statistics will not use any statistical information.
3429 Testing the high similarity condition will allow for an equivalent test to Wainberg
3430 et al. (2013). Therefore, Experiment 1 tested the following:

3431 **Hypothesis 6.2—Effect of statistics for negative anecdotes.** Participants
3432 will allocate capital equivalently to the target project when in the high similarity
3433 anecdote & statistics condition and when in the high similarity anecdote only
3434 condition without enhancing the statistics explanation.

3435 Participants with additional information explaining the importance of “scientific
3436 thinking” and statistical data may be less affected by anecdotes, as in the *judgment*
3437 *orientation II* condition in Wainberg (2018), here called the *anecdote & enhanced*
3438 *statistics condition*. Unlike the anecdote & enhanced statistics condition in Wainberg
3439 et al. (2013), the statistical information here is actually “enhanced” because of
3440 the accompanying text. Experiment 1 tests whether the effect from Wainberg
3441 (2018)—additional information protecting against anecdotal bias—would replicate
3442 in a capital allocation scenario. Therefore, Experiment 1 tested the following:

3443 **Hypothesis 6.3—Effect of enhanced statistics for negative anecdotes.**
3444 Participants will allocate more capital to the target project when in the high

6. Anecdote similarity moderates anecdotal bias in capital allocation

Table 6.1: Experiment 1 group allocation.

³⁴⁴⁵ similarity anecdote & enhanced statistics condition than when in the high similarity
³⁴⁴⁶ anecdote & statistics condition.

³⁴⁴⁷ 6.2.1 Method

³⁴⁴⁸ 6.2.1.1 Participants

³⁴⁴⁹ Two hundred and eighty-four people (197 female) were recruited from a Psy-
³⁴⁵⁰ chology undergraduate sample at The University of Sydney. Participants were
³⁴⁵¹ compensated with course credit. The average age was 20.84 ($SD = 4.93$, $min =$
³⁴⁵² 18, $max = 58$). Participants reported an average of 1.68 ($SD = 3.63$, $min = 0$,
³⁴⁵³ $max = 32$) years of work in a business setting, and an average of 0.81 ($SD = 1.57$,
³⁴⁵⁴ $min = 0$, $max = 12$) years of business education. The mean completion time was
³⁴⁵⁵ 22.24 ($SD = 97.45$, $min = 1.67$, $max = 1,101.48$) minutes. Table 6.1 shows the
³⁴⁵⁶ between-subjects condition allocation. Appendix C.1.1.1.1 describes the power
³⁴⁵⁷ analysis conducted to arrive at this sample size.

³⁴⁵⁸ 6.2.1.2 Materials

³⁴⁵⁹ 6.2.1.2.1 Instructions All participants initially saw general instructions that
³⁴⁶⁰ explained the task. The subsequent instructions that participants saw depended on
³⁴⁶¹ their experimental condition. Those in the anecdote only condition were told that
³⁴⁶² they will see a case study of a failed project and an analysis of why it failed. Those
³⁴⁶³ in the statistics only condition were told that they will see NPV and reliability

6. Anecdote similarity moderates anecdotal bias in capital allocation

3464 information as a part of the descriptions of the two focal projects. Participants were
3465 explained that these values were sourced from a study with a large sample. Those
3466 in the anecdote & statistics condition were given both of these instructions, and
3467 were also told that the information in the anecdote is subsumed in the data of the
3468 aggregated study. Those in the anecdote & enhanced statistics condition saw the
3469 same as those in the anecdote & statistics condition, but were subsequently given the
3470 explanation of scientific thinking that Wainberg (2018) used. Appendix C.1.1.2.1
3471 shows the instructions used in Experiment 1.

3472 **6.2.1.2.2 Allocation task** In the allocation task, participants allocated a
3473 percentage of a hypothetical budget between two projects that come from different
3474 businesses within a company. In this chapter, these two projects will be referred to
3475 as the *focal* projects. One of these projects will be referred to as the *target* project
3476 and the other as the *comparison* project. The target project was used as a reference
3477 for the similarity manipulation. That is, the anecdote was either high or low in
3478 similarity compared to the target project. Further, the data analyses presented
3479 in Section 6.2.2 used allocations to the target project as the DV. The comparison
3480 project was simply the other focal project to which participants were allocating. It
3481 was always a different type of project to both the target and anecdote projects.

3482 Participants were presented with information about each business' name, location,
3483 integration (vertical or horizontal), and organisational structure (centralised or
3484 decentralised). See Appendix C.1.1.2.2 for an explanation of these terms. Further,
3485 participants were presented with information about features of each project that they
3486 were told were available to managers before the time of investment. Participants in
3487 the anecdote only condition saw just this information (see Figure 6.1), while those
3488 in the statistics conditions saw this information along with measures of NPV and
3489 “Overall reliability rating” (see Figure 6.2). Participants entered their allocation
3490 data underneath this table, in two textboxes labelled *Project A allocation* and
3491 *Project B allocation*, respectively.

6. Anecdote similarity moderates anecdotal bias in capital allocation

Target projects

Allocate your budget between the following two projects using percentage values (the two values should sum to 100):

Relevant information	Project A	Project B
Business name	Enfuel	Microxy
Investment	oil well	microchip
Location	Texas, USA	Manchester, UK
Integration	vertical	horizontal
Structure	centralised	decentralised
Predicted project features	<ul style="list-style-type: none"> • Oil extracted: 2200L an hour • Time the machinery lasts before requiring maintenance: 8 years • Probability of finding oil: 88% • Type of well: onshore 	<ul style="list-style-type: none"> • Microchips produced: 4000 an hour • Usable semiconductor yield after testing: 60% • Compatible PCs in the market: 75% • Type of integrated circuit: digital

Project A allocation: %

Project B allocation: %

6. Anecdote similarity moderates anecdotal bias in capital allocation

3492 **6.2.1.2.3 Anecdote** Participants that were presented with an anecdote (those
3493 in either the anecdote only, anecdote & statistics, or anecdote & enhanced statistics
3494 conditions) saw a description of a business project and an accompanying “analysis.”
3495 Figures 6.3 and 6.4 show the anecdote display for those in the high and low similarity
3496 conditions, respectively. The project description had a similar layout to that of the
3497 focal projects. That is, it contained information about the business name, location,
3498 integration, and organisational structure of the business. It also detailed several
3499 predicted features of the project. Underneath this description was a paragraph of
3500 text that participants were told was an analysis of why the project failed. This text
3501 referenced each of the features in the description in order to justify the project failing.

3502 Those in the high similarity condition saw a description of a project from a
3503 business with the same type of investment as the target project (labelled Project
3504 A). All categorical attributes were identical to those in this target project, and
3505 the numerical attributes were all made to be lower. In the analysis, the numerical
3506 attributes were explained to have failed because they were not as high as certain cut-
3507 offs. Critically, these cut-offs were made to all be higher than the relevant values in
3508 Project A. This was done to make sure that the numerical attributes in the anecdote
3509 seem more relevant to those in Project A. For instance, for Project A, oil extraction
3510 was 2200L an hour, for the anecdote it was 2000L an hour, and the cutoff was 3000L
3511 an hour. As such, a failure of the anecdote because of an insufficient oil extraction
3512 rated will seem more relevant since they both share the state of being lower than
3513 the cut-off in the analysis. Note, however, that there was uncertainty about the
3514 generalisability of these cut-off values because the participants did not receive an
3515 explicit indication of whether these values were meant to generalise to other cases.

3516 **6.2.1.2.4 Follow-up questions** Participants that saw the anecdote were subse-
3517 quently presented with follow-up questions. They were asked how similar they believe
3518 the anecdote was to the target project, how relevant it was for their allocations,
3519 and how relevant it would be for judgements about other projects of that type.
3520 Figure C.7 in the appendix shows these questions.

6. Anecdote similarity moderates anecdotal bias in capital allocation

Case study

- Business details:
 - Business name: Refinera
 - Location: New Mexico, USA
 - Integration: vertical
- Investment: oil well
- Predicted project features:
 - Oil extracted: 2000L an hour
 - Time the machinery lasts before requiring maintenance: 7 years
 - Probability of finding oil: 80%
 - Type of well: onshore

Refinera struggled to establish itself in the regional market because of what scientists now know is a hydrocarbon shortage in the New Mexico area. A centralised organisational structure meant that key operational decisions were delayed with what needed to be a timely process. Being vertically integrated meant that these delays caused losses at the retail sites due to miscalculations of petrol supply. To make up for this, a post hoc analysis concluded that oil was needed to be extracted at a rate of 3000L an hour and sites have at least a 96% probability of finding oil before management approved the project. Further, machinery needed to have thought to last at least 10 years before requiring maintenance, because maintenance costs further offset the initial investment after the 7 years of development. Further, the well was quite susceptible to crude oil price changes due to it being an onshore well, and so added additional financial setbacks over the course of the project.

Figure 6.3: Anecdote display for those in the high alignment condition in Experiment 1.

6.2.1.3 Procedure

3521 Participants were introduced to the study through the general instructions and
3522 the specific instructions relevant to their condition. They were then presented with
3523 the allocation task, which included the anecdote analysis and description (for those
3524 not in the statistics condition) and the focal projects description. Those that saw
3525 an anecdote were subsequently shown the follow-up questions.

6.2.2 Results

6.2.2.1 The effect of similarity on anecdotal bias

3529 Anecdotal bias was tested by comparing the statistics only condition with both
3530 the high and the low similarity anecdote & (not enhanced) statistics conditions.

6. Anecdote similarity moderates anecdotal bias in capital allocation

Case study

- Business details:
 - Business name: Refinera
 - Location: Zhuhai, China
 - Integration: horizontal
- Investment: oil well
- Predicted project features:
 - Oil extracted: 1400L an hour
 - Time the machinery lasts before requiring maintenance: 5 years
 - Probability of finding oil: 56%
 - Type of well: offshore

Refinera struggled to establish itself in the regional market because of what scientists now know is a hydrocarbon shortage in the Zhuhai area. A decentralised organisational structure meant that communication across relevant business units was delayed with what needed to be a timely process. Being horizontally integrated meant that these delays caused losses at the other well sites due to a drain on the collective resources. To make up for this, a post hoc analysis concluded that oil was needed to be extracted at a rate of 2100L an hour and sites have at least a 67% probability of finding oil before management approved the project. Further, machinery needed to have thought to last at least 8 years before requiring maintenance, because maintenance costs further offset the initial investment after the 5 years of development. Further, the well was quite difficult to construct due to it being an offshore well, and so added additional financial setbacks over the course of the project.

Figure 6.4: Anecdote display for those in the low alignment condition in Experiment 1.

3531 Figure 6.5 shows these data. The omnibus one-way ANOVA test of these three
3532 conditions was significant, $F(2, 118) = 4.19$, $p = .018$, $\hat{\eta}_p^2 = .066$. Planned
3533 comparisons revealed that participants allocated more to the target project when
3534 seeing only statistics than when seeing the high similarity anecdote with statistics,
3535 $\Delta M = -12.31$, 95% CI $[-21.53, -3.09]$, $t(118) = -2.64$, $p = .009$; but not
3536 compared to seeing the low similarity anecdote with statistics, $\Delta M = -1.48$, 95%
3537 CI $[-10.75, 7.80]$, $t(118) = -0.31$, $p = .753$. These findings provide evidence of
3538 anecdotal bias only in the high similarity condition.

6. Anecdote similarity moderates anecdotal bias in capital allocation

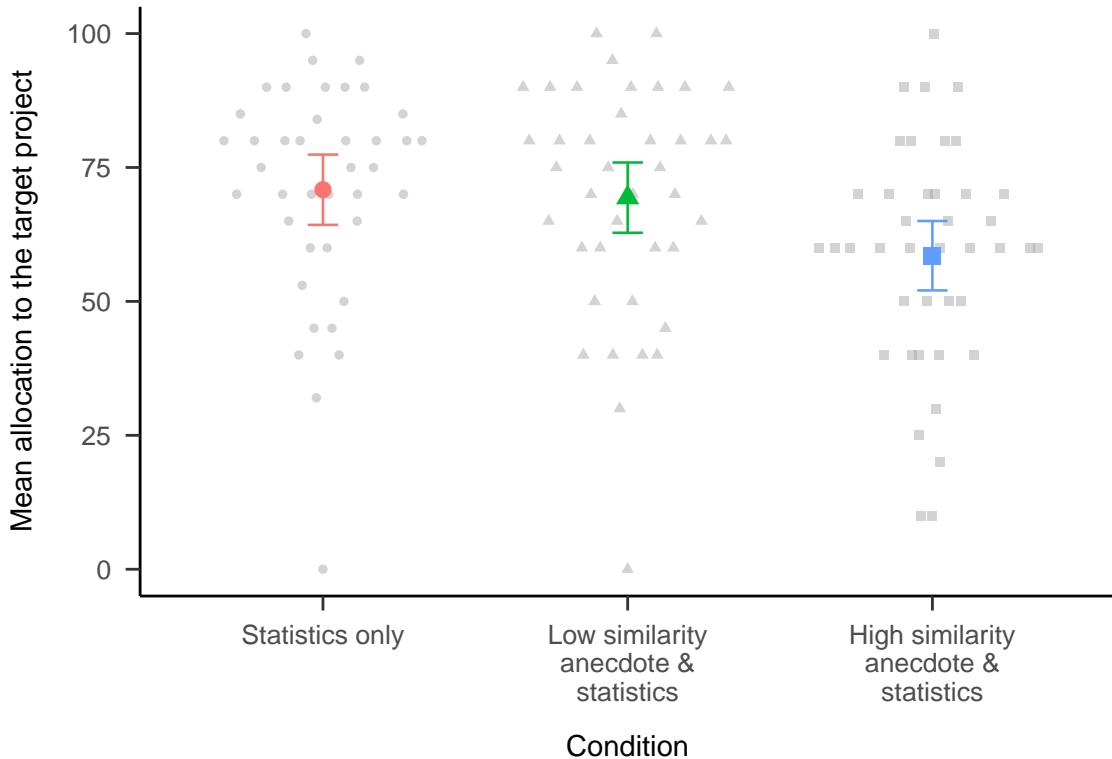

Figure 6.5: Mean allocation to the target project for the statistics only condition and the two anecdote & statistics conditions. Error bars represent 95% confidence intervals. Raw data are plotted in the background.

3539 6.2.2.2 The effect of enhanced statistics

3540 The effect of enhanced statistics was investigated by comparing the conditions
3541 in which participants saw an anecdote with statistics to the conditions in which
3542 they saw the same, but with enhanced statistics. Figure 6.6 shows these data. The
3543 two-way interaction between similarity and the two types of the anecdote & statistics
3544 condition was not significant, $M = 3.89$, 95% CI $[-8.86, 16.65]$, $t(238) = 0.60$,
3545 $p = .548$. Further, the main effect of anecdote & statistics condition (averaging
3546 over similarity) was also not significant, $\Delta M = -0.12$, 95% CI $[-6.50, 6.26]$,
3547 $t(238) = -0.04$, $p = .971$. This suggests that providing participants with instructions
3548 on how to think statistically is not sufficient to facilitate a focus on statistics.

3549 6.2.2.3 The effect of statistics

3550 A two-way ANOVA was conducted to investigate the interaction of similarity
3551 (low and high) and anecdote condition (anecdote only and statistics & anecdote,

6. Anecdote similarity moderates anecdotal bias in capital allocation

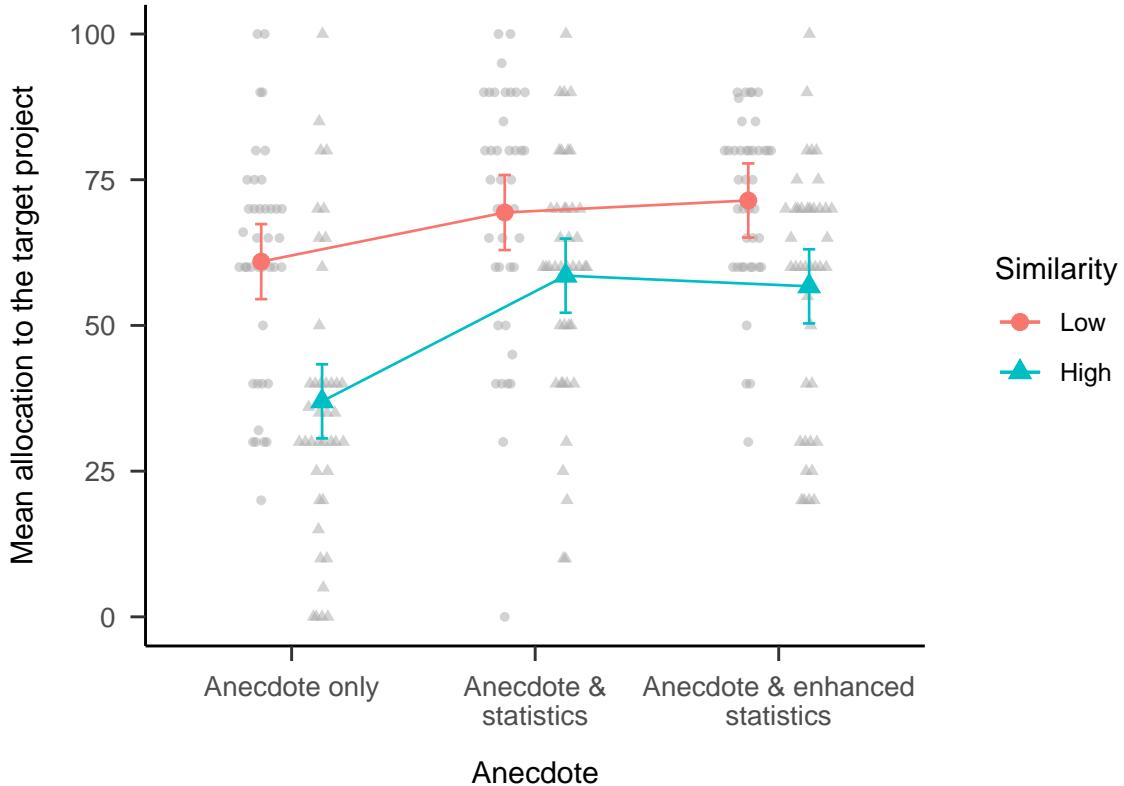

Figure 6.6: Mean allocation to the target project, by similarity and anecdote conditions (excluding the statistics only condition). Error bars represent 95% confidence intervals. Raw data are plotted in the background.

3552 excluding the anecdote & enhanced statistics condition). Figure 6.6 shows these data.
 3553 This identified the role of statistics in people's allocations. The interaction between
 3554 anecdote condition and similarity (excluding the enhanced statistics condition)
 3555 was significant, $M = -13.14$, 95% CI $[-25.93, -0.34]$, $t(238) = -2.02$, $p = .044$.
 3556 Specifically, the difference between allocations when only seeing an anecdote and
 3557 seeing the anecdote with statistics was greater when the anecdote was similar,
 3558 $\Delta M = -21.56$, 95% CI $[-32.33, -10.80]$, $t(238) = -4.72$, $p < .001$; compared
 3559 to when it was dissimilar, $\Delta M = -8.43$, 95% CI $[-19.32, 2.47]$, $t(238) = -1.82$,
 3560 $p = .164$. These findings provide evidence of partial anecdotal bias in the high
 3561 similarity condition, since the anecdote & statistics condition was lower than the
 3562 statistics only condition (shown above), but higher than the anecdote only condition.

6. Anecdote similarity moderates anecdotal bias in capital allocation

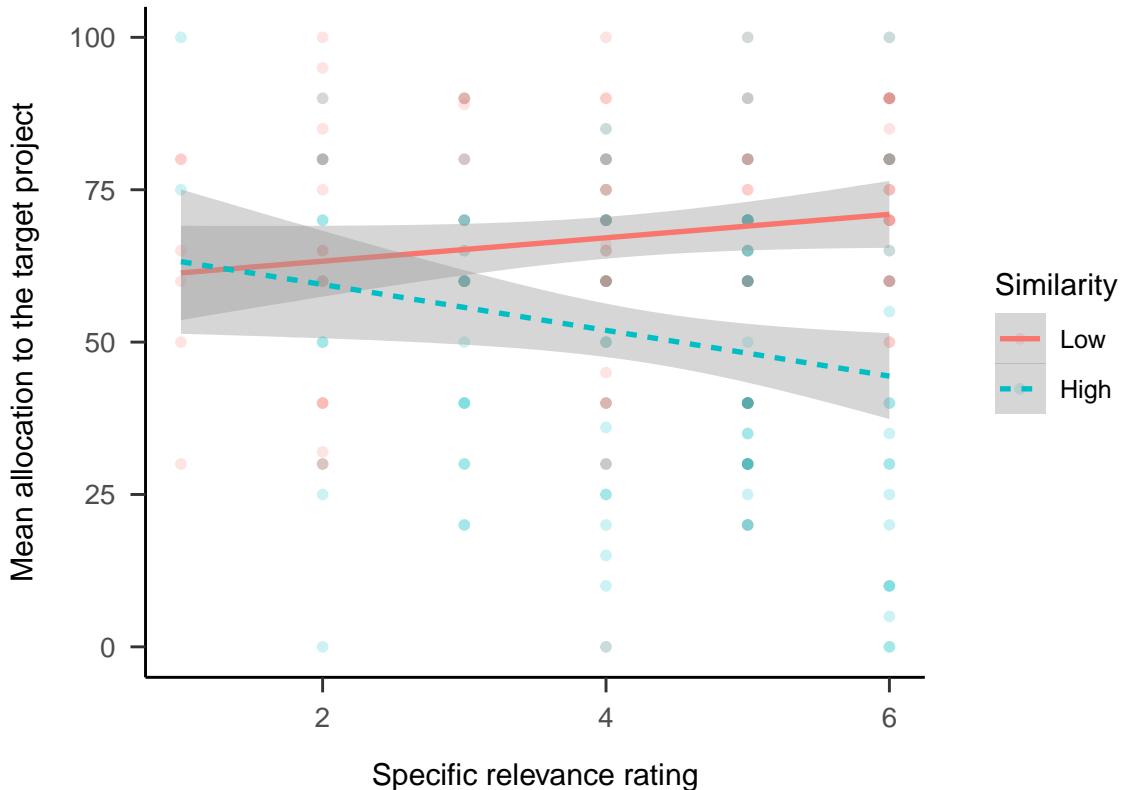

Figure 6.7: Mean allocation to the target project, by specific relevance rating and similarity condition. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals. Raw data are plotted in the background.

3563 6.2.2.4 Relevance ratings

3564 Regression analyses were conducted to determine the relationship between
 3565 allocations and the follow-up relevance ratings. As seen in Figure 6.7 the spe-
 3566 cific relevance ratings interacted with similarity condition, $b = -2.84$, 95% CI
 3567 $[-4.80, -0.87]$, $t(240) = -2.85$, $p = .005$. It appears that specific relevance ratings
 3568 were related to allocations, but only in the high similarity condition. Further,
 3569 there were no significant associations with the general relevance ratings. This
 3570 suggests that people were reasoning about the connection between the anecdote
 3571 and target, as opposed to simply reacting to the failed project and associating
 3572 that with that project's industry.

6. Anecdote similarity moderates anecdotal bias in capital allocation

3573 6.2.3 Discussion

3574 Hypothesis 6.1 was supported. Participants allocated less capital when seeing
3575 the anecdote with statistics than when seeing the statistics alone. This effect was
3576 moderated by similarity, however, as it was seen in the high similarity condition,
3577 but not in the low similarity condition. This shows that while anecdotal bias
3578 exists when the anecdote is similar, participants are not influenced when the causal
3579 mechanisms do not match. Contrary to Hypothesis 6.2, despite being influenced by
3580 the anecdote, participants still made some use of the statistics. This is different
3581 from Wainberg et al. (2013), who found no difference between an anecdote only
3582 and an anecdote & statistics condition, indicating a complete effect of anecdotal
3583 bias. Hypothesis 6.3 was also not supported, as the added enhanced statistical
3584 language used to encourage participants to use the statistical information did not
3585 contribute to reducing participants' reliance on anecdotes.

3586 Experiment 1 was limited because it only considered an anecdote with a *negative*
3587 valence. That is, the case study was of a project that failed. In real life, however,
3588 these case studies are often ones with *positive* valence. That is, a story of a successful
3589 company. In fact, in business, the anecdotes that are used might be more likely to
3590 be positive, because of survivorship bias. Jaramillo et al. (2019) found an anecdotal
3591 bias effect in negative anecdotes, but not in positive anecdotes. This may be
3592 because the stimuli consisted of medical decisions and in this domain a loss of
3593 health may be felt stronger than an equivalent gain of health. Experiment 2 added
3594 a condition with a positive anecdote, in order to investigate whether anecdote
3595 valence will impact the anecdotal bias effect.

3596 It was unclear if the effects found in Experiment 1 were related to participants'
3597 perceptions of the type of sampling used in selecting the anecdotes. The instructions
3598 in Experiment 1 did not explain how the anecdote displayed to participants was
3599 chosen. Whether sampling is believed to be intentional or random has been shown
3600 to affect people's decision-making (e.g., Hayes et al., 2019). In the case of the
3601 current experiments, the sampling assumption changes the extent to which it is

6. Anecdote similarity moderates anecdotal bias in capital allocation

3602 rational to use the anecdote or not. It may be rational to choose the anecdote over
3603 the aggregated data if 1. the anecdote was not sampled randomly from the pool
3604 of anecdotes, and 2. the anecdote is more similar to the target project than any
3605 of the other anecdotes in the pool in relevant ways. That is, if the anecdote was
3606 chosen because of its high relevance to the target project, it would be irrational
3607 to ignore it. In Experiment 1 it was unclear whether participants might have held
3608 these beliefs. In order to control for these assumptions, in Experiment 2, text was
3609 added to the instructions that clarified that the anecdote 1. was sampled randomly
3610 from the pool of anecdotes, and 2. is not significantly more similar to the target
3611 project than any of the other anecdotes in the pool.

3612 6.3 Experiment 2

3613 Experiment 1 replicated the anecdotal bias effect found in the literature. That is,
3614 people used an anecdote more when presented with conflicting statistics than with
3615 anecdote alone and less than with statistics alone. However, anecdote similarity
3616 moderated this effect, such that anecdotal bias was stronger when the anecdote
3617 was similar to the current task, than when it was dissimilar. Experiment 1
3618 only used a negative anecdote because previous research found anecdotal bias
3619 for negative, but not for positive anecdotes (Jaramillo et al., 2019). However,
3620 Jaramillo et al. (2019) considered medical decision-making, so this effect of anecdote
3621 valence may be different in a business context. In the study, the positive anecdote
3622 involved a treatment that led to a reduction in symptoms and the negative anecdote
3623 involved symptoms persisting. This framing might mean participants represented
3624 the positive anecdote as a return to a reference point and the negative anecdote
3625 as a continuation of a reduction in well-being, relative to the reference point. In
3626 business, however, both successful and failed business projects represent a deviation
3627 from a reference point. To test this difference further, Experiment 2 added an
3628 anecdote valence manipulation

6. Anecdote similarity moderates anecdotal bias in capital allocation

3629 In order to increase the experiment's power, anecdote valence and anecdote
3630 similarity were manipulated within-subjects. Further, Experiment 2 did not include
3631 the anecdote & enhanced statistics manipulation, because Experiment 1 did not
3632 find evidence for its effect. All participants saw the statistics only condition, as
3633 it did not contain an anecdote, and therefore did not need to be manipulated
3634 between-subjects. Each participant therefore saw five displays: one display for the
3635 statistics only condition; and four displays for either the anecdote only condition,
3636 or the anecdote & statistics condition. These four anecdote displays consisted of
3637 the similarity (low and high) \times valence (negative and positive) conditions.

3638 Experiment 1 did not clarify certain assumptions about the distribution from
3639 which the anecdote was sampled. In Experiment 2, participants were told that
3640 the anecdote was sampled randomly and that it was not uniquely similar to the
3641 target project. This should lead to a reliance on the statistical evidence, regardless
3642 of the anecdote's similarity. However, people often struggle to use statistical
3643 concepts presented descriptively, as seen in the enhanced statistics condition in
3644 Experiment 1, the variance neglect in Chapter 4, and the lack of risk aggregation
3645 in descriptive risky choice as in Chapter 2. Therefore, it was expected that the
3646 effects of Experiment 1 will replicate in the negative valence condition. Further it
3647 was expected that there will be a reverse effect in the positive valence condition.
3648 The appendix shows a simulation of the hypothesised effects (see Figures C.13
3649 and C.14). Therefore, Experiment 2 tested the following:

3650 **Hypothesis 6.4—Overall effect.** Three-way interaction of similarity \times valence
3651 \times anecdote, excluding statistics only

3652 The main effect of interest was the moderation of anecdotal bias by similar-
3653 ity. Therefore, as well as again testing Hypothesis 6.1 for negative anecdotes,
3654 Experiment 2 tested the following:

3655 **Hypothesis 6.5—Anecdotal bias moderated by similarity for positive
3656 anecdotes.** For positive anecdotes, allocations will be higher in the statistics only
3657 condition than in both the anecdote & statistics conditions (high and low similarity).

6. Anecdote similarity moderates anecdotal bias in capital allocation

3658 Within these two anecdote & statistics conditions, allocations will be higher when
3659 the anecdote is similar than when it is dissimilar.

3660 Contrary to both Wainberg et al. (2013) and Hypothesis 6.2, Experiment 1 found
3661 that participants do somewhat integrate statistics in their decisions. This effect was
3662 expected to replicate in Experiment 2. Therefore, Experiment 2 tested the following:

3663 **Hypothesis 6.6—Effect of statistics for negative anecdotes.** For negative
3664 anecdotes, allocations will be higher for the high similarity anecdote & statistics
3665 condition than for the high similarity anecdote only condition.

3666 **Hypothesis 6.7—Effect of statistics for positive anecdotes.** For positive
3667 anecdotes, allocations will be higher for the high similarity anecdote only condition
3668 than for the high similarity statistics & anecdote condition.

3669 6.3.1 Method

3670 6.3.1.1 Participants

3671 Ninety-six people (50 female) were recruited from the online recruitment platform
3672 Prolific. Participants were compensated at a rate of £5 an hour. The average age
3673 was 41.69 ($SD = 11.29$, $min = 27$, $max = 74$). Participants reported an average
3674 of 7.19 ($SD = 8.34$, $min = 0$, $max = 43$) years of work in a business setting, and
3675 an average of 3.91 ($SD = 7.67$, $min = 0$, $max = 50$) years of business education.
3676 The mean completion time was 14.98 ($SD = 8.84$, $min = 2.57$, $max = 58.71$)
3677 minutes. Table 6.2 shows the between-subjects condition allocation. Similarity and
3678 valence were manipulated within-subjects. Therefore, each participant was in one
3679 of two between-subjects anecdote conditions, and saw five displays (statistics only,
3680 and one for each of the four similarity and valence conditions). Appendix C.2.1.1.1
3681 describes the power analysis conducted to arrive at this sample size.

Anecdote between	N
Anecdote & statistics	48
Anecdote only	48
Total	96

6.3.1.2 Materials

6.3.1.2.1 Instructions Participants were shown similar instructions to Experiment 1 (see Section 6.2.1.2.1). The general instructions page included a test of the basic information expressed in the instructions. This test also functioned as an attention check. As in Experiment 1, participants also saw instructions that were specific to their condition. These were shown on the same page as the rest of the project display, above the case study and focal projects. The instructions clarified both that the anecdote was sampled randomly and that the anecdotes in the pool were all equally similar to the target project. Appendix C.2.1.2.1 shows the instructions used in Experiment 2.

6.3.1.2.2 Allocation task As in Experiment 1, the allocation task included a description and analysis of an anecdote (except for those in the anecdote only condition) and a project display with a table describing the two focal projects. Figures 6.8 and 6.9 show the anecdote and focal projects, respectively, for the negative valence low similarity condition. Figures 6.10 and 6.11 show the anecdote and focal projects, respectively, for the positive valence high similarity conditions. In the statistics only condition, participants only saw the focal projects display. Appendix C.2.1.2.2 details the counterbalancing and randomisation used in the experiment.

6.3.1.2.3 Interstitial Before each display, participants saw an “interstitial” page, whose role was 1. to introduce the next display, and 2. to provide an attention check (not required to answer, so can be skipped if the interstitial text isn’t read). See Figure C.21 in the appendix for an example.

6. Anecdote similarity moderates anecdotal bias in capital allocation

Case study

Cweb struggled to establish itself in the regional market because of changes in privacy laws (that reduced consumer confidence in the business' apps) in the Mumbai area. A centralised organisational structure meant that poor performers took longer to be replaced, so some tasks needed considerable revision. Being vertically integrated meant that the project was reliant on in-house manufacturing and so was slow to adopt the newest technologies used by competitors. A post hoc analysis concluded that, to make up for these issues, the developers needed to write at least 800 lines a day and the application needed to be certified with a security rating of at least 68%. Further, the number of potential first-year customers needed to be at least 2 million. Further, the problems in the application were slow to solve because of the lack of large-scale quantitative data due to it being for enterprise, and so added additional financial setbacks over the course of the project.

- Business details:
 - Business name: Cweb
 - Location: Mumbai, India
 - Integration: vertical
 - Structure: centralised
- Investment: software
- Predicted project features:
 - Code written: 600 lines a day
 - Security rating: 51%
 - Number of potential customers in first year: 2 million
 - Target users: enterprise

Figure 6.8: An example of the anecdote display in the negative valence, low similarity condition of Experiment 2.

3704 **6.3.1.2.4 Follow-up questions** Participants were shown similar follow-up
3705 questions as in Experiment 1, except that here the rating scales were 1-7, instead of 1-
3706 6. See Figure C.20 in the appendix for an example of the follow-up questions display.

3707 **6.3.1.3 Procedure**

3708 Participants were introduced to the study through the general instructions page.
3709 They then saw five sets of two pages (in randomised order). Each set contained
3710 two pages: the allocation task and a follow-up questions page (except for the
3711 anecdotes only condition, in which participants did not see the follow-up questions

6. Anecdote similarity moderates anecdotal bias in capital allocation

Target projects		
Allocate your budget between the following two projects using percentage values (the two values should sum to 100):		
Relevant information	Project 1	Project 2
Business name	Codeck	Enfuel
Project type	software	oil well
Location	Austin, USA	Houston, USA
Integration	horizontal	vertical
Structure	decentralised	centralised
Predicted project features	<ul style="list-style-type: none"> • Code written: 1000 lines a day • Security rating: 85% • Number of potential customers in first year: 3 million • Target users: ordinary consumers 	<ul style="list-style-type: none"> • Oil extracted: 2000L an hour • Time the machinery lasts before requiring maintenance: 7 years • Probability of finding oil: 80% • Type of well: onshore
Project allocation (%)	Allocation: <input type="text" value=""/>	Allocation: <input type="text" value=""/>
Overall reliability rating (%)	91	90
NPV (\$)	901	100

Figure 6.9: An example of the focal projects in the negative valence, low similarity condition of Experiment 2.

6. Anecdote similarity moderates anecdotal bias in capital allocation

Case study

Microxy performed really well in the regional market because of decreased silicon taxes in the Montreal area. A decentralised organisational structure meant that the individual teams had greater autonomy to complete their tasks, increasing the efficiency of important project stages. Being horizontally integrated meant that the project can be easily marketed to the customer base of the other business units in the company. A post hoc analysis concluded that, to take advantage of these benefits, the microchips needed to be produced at a rate of at least 3200 an hour and the semiconductor yield needed to be at least 57%. Further, the percent of compatible devices needed to be at least 71%. Further, the chip has a relatively low power consumption due to it operating Reduced Instruction Set Computing, and so added additional financial resilience over the course of the project.

- Business details:
 - Business name: Microxy
 - Location: Montreal, Canada
 - Integration: horizontal
 - Structure: decentralised
- Investment: microchip
- Predicted project features:
 - Microchips produced: 4800 an hour
 - Usable semiconductor yield after testing: 63%
 - Compatible devices in the market: 79%
 - Type of chip architecture: Reduced Instruction Set Computing

Figure 6.10: An example of an anecdote display in the positive valence, high similarity condition of Experiment 2.

3712 page). Each allocation task page contained specific instructions relevant to the
3713 condition, followed by the anecdote analysis and description, and the description
3714 for the two focal projects. The only exception was the statistics only display, for
3715 which there was no anecdote description or analysis.

3716 6.3.2 Results

3717 Only the data that were relevant to the Experiment 2 hypotheses are reported
3718 here. See Appendix C.2.2 for manipulation check analyses, and analyses of the
3719 follow-up rating data.

6. Anecdote similarity moderates anecdotal bias in capital allocation

Target projects		
Allocate your budget between the following two projects using percentage values (the two values should sum to 100):		
Relevant information	Project 1	Project 2
Business name	Solistics	Altchip
Project type	shipping logistics	microchip
Location	Kuala Lumpur, Malaysia	Toronto, Canada
Integration	vertical	horizontal
Structure	centralised	decentralised
Predicted project features	<ul style="list-style-type: none"> • Packages shipped: 800 a week • Number of orders that do not spend time in a bottleneck: 400 a day • Average accuracy of shipments: 90% • Shipping type: parcel 	<ul style="list-style-type: none"> • Microchips produced: 4000 an hour • Usable semiconductor yield after testing: 60% • Compatible devices in the market: 75% • Type of chip architecture: Reduced Instruction Set Computing

Overall reliability rating (%)	93	90
NPV (\$)	905	105

Figure 6.11: An example of the focal projects in the positive valence, high similarity condition of Experiment 2.

6. Anecdote similarity moderates anecdotal bias in capital allocation

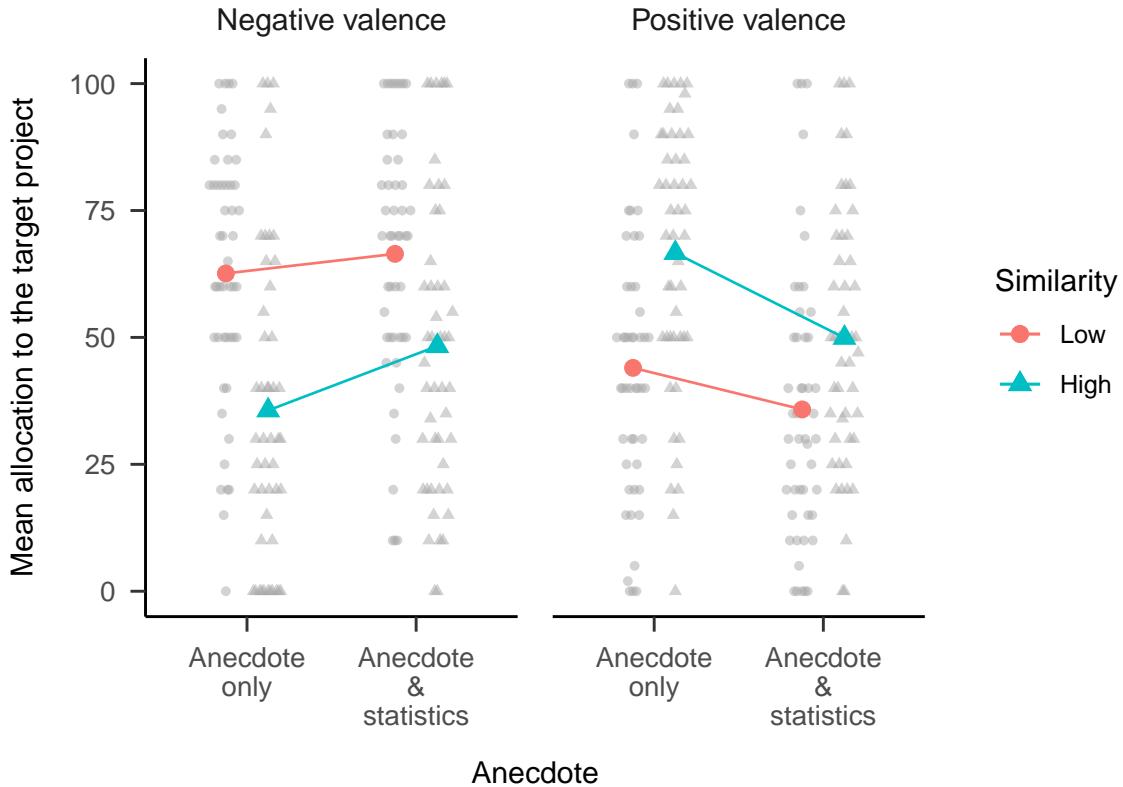

Figure 6.12: Mean allocation to the target project, by similarity and valence conditions. In mixed factorial designs, error bars cannot be used to make inferences by “eye” across all conditions. Therefore, error bars are not included. Raw data are plotted in the background.

3720 6.3.2.1 Overall effect of manipulations

3721 As seen in Figure 6.12, the similarity \times valence \times anecdote interaction (excluding
 3722 the statistics only condition) was not significant, $F(1, 94) = 3.42, p = .067, \hat{\eta}_p^2 = .035$.
 3723 However, the similarity \times valence interaction was significant, $F(1, 94) = 76.41$,
 3724 $p < .001, \hat{\eta}_p^2 = .448$, as was the anecdote \times valence interaction, $F(1, 94) = 10.11, p =$
 3725 $.002, \hat{\eta}_p^2 = .097$. The analyses below investigated the specific hypothesised effects.

3726 6.3.2.2 Anecdotal bias moderated by similarity

3727 To investigate whether anecdotal bias was moderated by similarity, a difference
 3728 measure was calculated between each participant’s allocation to the statistics only
 3729 condition and their allocation to each of the two anecdote & statistics conditions
 3730 (high and low similarity). The statistics only comparison value was different for
 3731 each valence condition to create equivalent comparisons. For negative valence, the

6. Anecdote similarity moderates anecdotal bias in capital allocation

allocation to the high NPV project was used; while for positive valence, the allocation to the low NPV project was used. Figure 6.13 shows these data. The similarity \times valence interaction was significant, $F(1, 47) = 30.66, p < .001, \hat{\eta}_p^2 = .395$, as was the main effect of valence, $F(1, 47) = 9.85, p = .003, \hat{\eta}_p^2 = .173$. The main effect of similarity was not significant, $F(1, 47) = 0.53, p = .469, \hat{\eta}_p^2 = .011$.

The effect of the anecdote is represented differently for each valence condition. As such, the interaction was analysed further by comparing the two similarity conditions for each valence condition. For negative anecdotes, the statistical values (e.g., NPV) associated with the target project were higher than those for the comparison project. If participants were influenced by the negative anecdote they would therefore allocate less to the target. For negative anecdotes, a lower allocation to the target project is represented in Figure 6.13 as a positive value—the difference in allocation from when the participant did not see an anecdote. For positive anecdotes, the statistics were lower for the target project, so an influence of the anecdote is seen as a negative value in Figure 6.13. A moderation of the anecdotal bias effect by similarity for negative anecdotes would suggest a higher difference score in high similarity than in low similarity. That is, more influence of the anecdote when it is similar than when it is dissimilar. For positive anecdotes a moderation would suggest the reverse: a higher difference score in low similarity than in high similarity.

For negative anecdotes, the allocation difference was greater when the anecdote was similar to the target than when it was dissimilar, $\Delta M = -18.17, 95\% \text{ CI } [-26.17, -10.17], t(93.80) = -4.51, p < .001$. For positive anecdotes, the allocation difference was greater when the anecdote was dissimilar to the target than when it was similar, $\Delta M = 14.10, 95\% \text{ CI } [6.10, 22.11], t(93.80) = 3.50, p = .001$. This provides evidence for the moderation of anecdotal bias by similarity for both negative and positive anecdotes. People seem to be sensitive to the relevance of the anecdote to the target problem.

6. Anecdote similarity moderates anecdotal bias in capital allocation

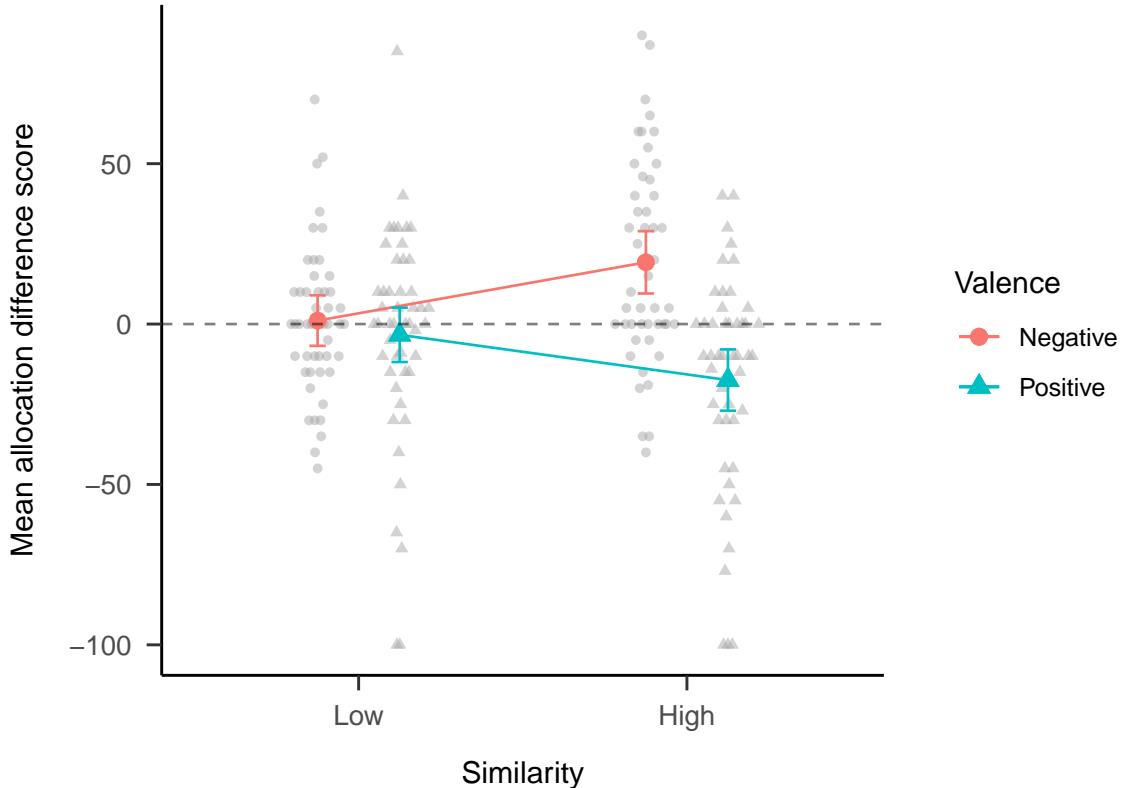

Figure 6.13: Mean allocation difference between the statistics only condition and the anecdote & statistics condition, by similarity and valence conditions. The horizontal dashed line shows the point in which the two allocations were equivalent. Values that are higher than this line represent participants that allocated more when seeing only the statistics than when seeing the statistics with an anecdote. Error bars represent 95% confidence intervals, calculated from the within-subjects SEs using the method from Cousineau and O'Brien (2014). Raw data are plotted in the background.

3759 6.3.2.3 Effect of statistics

3760 As in Experiment 1, Experiment 2 investigated the extent to which the statistical
 3761 information influenced participants' allocations. As seen in Figure 6.12, for negative
 3762 anecdotes, participants allocated more to the high similarity anecdote & statistics
 3763 project than those in the high similarity anecdote only condition, $\Delta M = -12.67$,
 3764 95% CI $[-23.53, -1.81]$, $t(336.36) = -2.29$, $p = .022$. When in the positive valence
 3765 condition, they allocated more to the high similarity anecdote only condition than
 3766 those in the high similarity anecdote & statistics condition, $\Delta M = 16.71$, 95% CI
 3767 $[5.85, 27.57]$, $t(336.36) = 3.03$, $p = .003$. This provides evidence for the influence of
 3768 statistics on participants' allocations for both negative and positive anecdotes.

6. Anecdote similarity moderates anecdotal bias in capital allocation

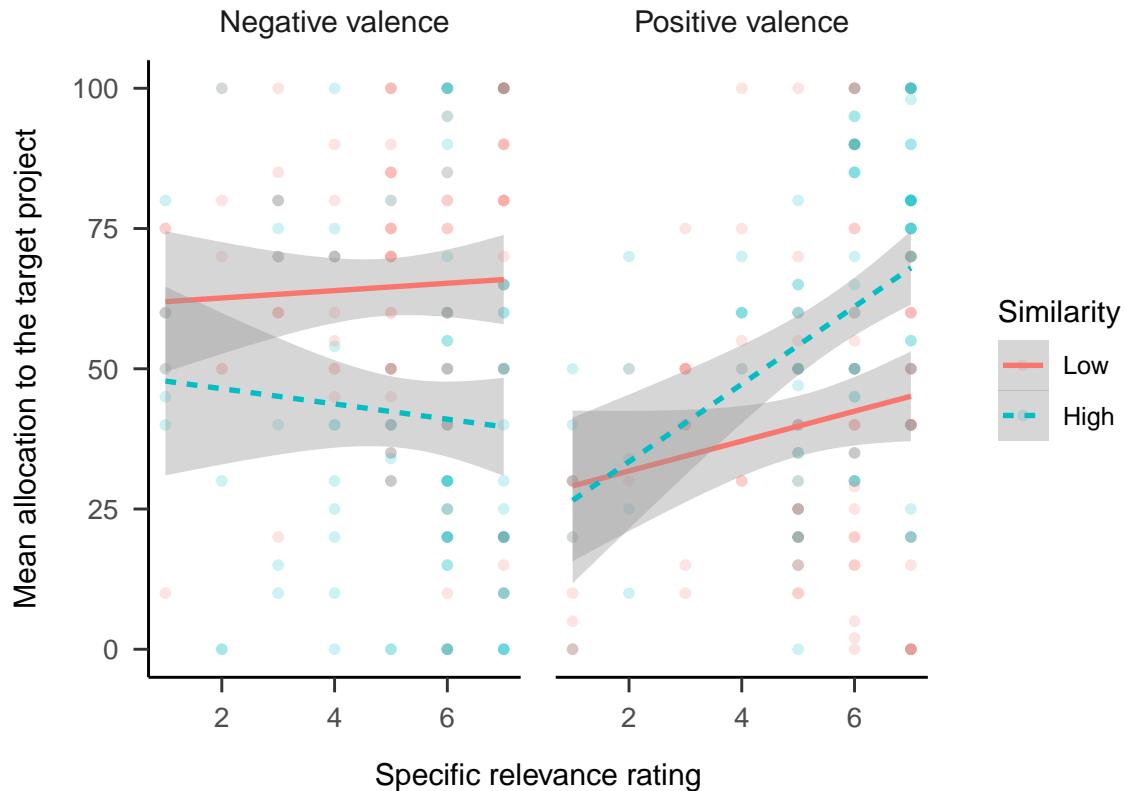

Figure 6.14: Mean allocation to the target project, by specific relevance rating, similarity condition, and valence condition. LOESS method was used for smoothing over trials and the shading represents 95% confidence intervals. Raw data are plotted in the background.

3769 6.3.2.4 Relevance ratings

3770 Regression analyses were conducted to determine the relationship between
 3771 allocations and the follow-up relevance ratings. Figure 6.14 shows these data. While
 3772 the specific relevance ratings for negative anecdotes showed the same trends as in
 3773 Experiment 1, the interaction was not significant. Similarly, the ratings trends for
 3774 positive anecdotes were as hypothesised, but their interaction not significant. It
 3775 appears that specific relevance ratings were related to allocations, but only in the
 3776 high similarity condition. Further, there were no significant associations with the
 3777 general relevance ratings. This provides limited evidence that people were reasoning
 3778 about the connection between the anecdote and target.

6. Anecdote similarity moderates anecdotal bias in capital allocation

3779 6.3.3 Discussion

3780 Hypotheses 6.1 and 6.5 were supported, as participants showed a stronger
3781 anecdotal bias effect when the anecdote was more similar to the target project,
3782 for both positive and negative anecdotes. Further, as per Hypotheses 6.6 and 6.7,
3783 participants incorporated the statistical information into their judgements, for both
3784 negative and positive anecdotes. Unlike in Experiment 1, the relevance rating data
3785 did not provide as clear indication that participants were using only the specific
3786 project information rather than merely its industry.

3787 Experiment 2 therefore found that, unlike in the medical domain, the effect
3788 of anecdotes in financial decision-making does not depend on anecdote valence.
3789 Further, as in Experiment 1, and unlike in Wainberg et al. (2013), the anecdotal
3790 bias effect does not seem to be complete, with statistics still playing some role in
3791 participants' decisions despite the effect of the anecdote.

3792 6.4 General discussion

3793 Most of the hypotheses were supported. This chapter found that, in a capital
3794 allocation context, people's decisions are influenced by anecdotes even when
3795 aggregated data are available. There were three novel findings: 1. the anecdotal
3796 bias effect was only seen when participants considered the anecdote as sufficiently
3797 relevant to the target project, 2. participants integrated statistics in their decisions,
3798 and 3. these effects were found in both negative and positive anecdotes. Further,
3799 people did not consider verbal sample distribution information, which could have
3800 helped to moderate their decisions. This is surprising since other work showed that
3801 generalisations are sensitive to sampling (Carvalho et al., 2021).

3802 The first novel finding from these experiments was that participants moderated
3803 their use of anecdotal evidence. Specifically, when the anecdote appeared to be
3804 causally relevant, participants used it in their decisions. However, when it appeared
3805 irrelevant, participants relied on statistics almost entirely. The findings in the
3806 high similarity condition are largely congruent with findings from other work

6. Anecdote similarity moderates anecdotal bias in capital allocation

3807 investigating anecdotal bias in business decision-making. As in Wainberg et al.
3808 (2013) and Wainberg (2018), this chapter found that people allocated less capital
3809 to a project that is successful according to statistical evidence co-presented with
3810 contradictory similar anecdote, than to a project with the statistics alone.

3811 It seems that participants made the distinction between the low and high
3812 similarity conditions based on the underlying structure of the anecdote. The low
3813 similarity condition always consisted of the same project type, for each domain,
3814 as in the high similarity condition. For instance, in one variation, both the high
3815 and low similarity anecdotes involved oil well projects. However, the high similarity
3816 anecdotes also matched with the target project on a number of specific features.
3817 This means that participants were sensitive to the specific information presented to
3818 them in the anecdote description and analysis, and did not simply use the project
3819 type for their inferences. Further, participants' answers to the follow up questions
3820 indicated that they did not consider the anecdote to be necessarily relevant to
3821 other projects from the same industry. In other words, participants did not appear
3822 to carelessly use anecdotal evidence in their decisions, but instead appeared to
3823 carefully consider the anecdote based on its particular causal structure.

3824 The second novel finding from these experiments was that participants that saw
3825 the statistics with anecdotal evidence did not completely disregard the statistical
3826 measures. Wainberg et al. (2013) found a complete effect of anecdotal bias, because
3827 in their study the anecdote only and anecdote & statistics conditions were equivalent.
3828 This meant that the statistics they provided had a negligible effect on participants'
3829 decisions. The experiments in this chapter, on the other hand, showed a partial
3830 anecdotal bias effect, seen as a difference in allocations between the anecdote only
3831 and anecdote & statistics conditions. It seems as if participants integrated the
3832 anecdotal information with the statistical information. This suggests that people's
3833 evaluation of evidence might be more sensitive than previously thought.

3834 The discrepancy between these results and those in Wainberg et al. (2013) might
3835 be a result of the sampled population. Since Freling et al. (2020) found a stronger
3836 effect of anecdote when decisions were more personally relevant, the manager sample

6. Anecdote similarity moderates anecdotal bias in capital allocation

3837 in Wainberg et al. (2013) may have simply been more personally invested in the task
3838 than the laypeople in the experiments in this chapter. Similarly, Yang et al. (2015)
3839 found that anxiety increases anecdotal bias in risky choice. The discrepancy might
3840 also, however, be due to the anecdote & statistics condition not being equivalent
3841 between Wainberg et al. (2013) and the present work. Specifically, the statistics
3842 shown in the anecdote & statistics condition in Wainberg et al. (2013) were not the
3843 same ones that were shown in the same study's statistics only condition, unlike in
3844 both the present experiments and Wainberg (2018). Instead, it was the anecdote &
3845 enhanced statistics condition that contained the same statistics as in the statistics
3846 only condition. This suggests that people only integrate statistics when they are
3847 sufficiently clear and no further interpretation is required.

3848 The third novel finding from these experiments was that anecdotal bias was found
3849 in both negative and positive anecdotes. Most studies in the literature considered
3850 anecdotes that involve an example with negative consequences (a *negative* anecdote).
3851 For instance, a medication that does not treat the symptoms of an illness. However,
3852 there is not much work in the literature that involves an anecdote with positive
3853 consequences (a *positive* anecdote). Jaramillo et al. (2019) found an asymmetry
3854 in the effect of the anecdote, such that the effect was stronger when a person in
3855 a description did not get better after a medication (negative), compared to when
3856 they did get better (positive). The present experiments found a more symmetrical
3857 effect, such that both the effects of the moderated anecdotal bias and the influence
3858 of statistics were found in both valence conditions.

3859 The difference between the findings from this chapter and those from Jaramillo
3860 et al. (2019) might be due to the negative anecdote in their experiment representing a
3861 persistence in a negative shift from the status quo (of not being sick). In the business
3862 domain, both the positive and negative anecdotes represent shifts from the status
3863 quo (of the company's financial position). Regardless, it is still surprising not to find
3864 an asymmetry because of the predictions of prospect theory. Loss aversion suggests
3865 that participants would have avoided the projects associated with the negative
3866 anecdotes more than they would have chosen those associated with the positive

6. Anecdote similarity moderates anecdotal bias in capital allocation

3867 anecdotes. On the other hand, each choice was associated with the conflicting
3868 statistical information, so this may cancel out the change from the reference point.
3869 Future research should use more realistic incentives in order to investigate this effect
3870 further. Doing this will also increase the ecological validity of the rest of the findings.

3871 6.4.1 Theoretical implications

3872 This chapter adds to the current understanding of the way people use different
3873 forms of evidence in their decision-making. Previous work mostly investigated the
3874 relative influence of statistics and anecdotes by comparing anecdote and statistics
3875 conditions. The current work shows that comparing a joint anecdote & statistics
3876 condition to both an anecdote only and statistics only condition allows for a more
3877 specific representation of participants' anecdotal bias. The influence of anecdote
3878 can be seen in the comparison between statistics only and the anecdote & statistics
3879 condition, but the effect of statistics can be seen in the comparison between the
3880 combined condition and the anecdote only condition. These two effects allow
3881 to determine the independent influence of anecdote and statistics, respectively.
3882 Further use of such a design in future research might help to further understand
3883 the conditions under which these types of evidence are used.

3884 It seems that in some of the anecdotal bias literature there is an assumption
3885 that using anecdotal evidence over statistical evidence is necessarily irrational. This
3886 likely arises from examples from the medical domain in which such decisions are
3887 indeed irrational (e.g., believing that vaccines cause certain disorders despite the
3888 available evidence). In such cases, people over-rely on anecdotes and should be
3889 relying more on aggregated data. However, a case could be made for a rational
3890 use of anecdote based on the similarity of the anecdote to the target. For instance,
3891 there are times in which an anecdote is so similar to the target situation (e.g., the
3892 identical twin example discussed in Section 6.1.3) that it would be unwise not to
3893 consider the anecdote. That is, the use of anecdote should depend on both 1. the
3894 extent of underlying structural similarity between it and the target problem, and
3895 2. the distribution of this similarity across cases in the sample from which the

6. Anecdote similarity moderates anecdotal bias in capital allocation

3896 anecdote was sampled. People should use an anecdote when causal structure is
3897 significantly more relevant than other cases in available data.

3898 However, similarity can also be misleading. For instance, if a case is highly
3899 similar, but not along some key hidden dimension that is the real causal mechanism
3900 to care about, then using the anecdote may be the wrong thing to do. What seems
3901 to be important is a sensitivity to relational, rather than surface level similarity.
3902 Future research should further investigate how varying the assumptions that people
3903 have about sampling from a data set of anecdotes influences their anecdotal bias.
3904 Such assumptions can include the size of the sample, the shape of the distribution,
3905 and where in the distribution the anecdote came from. Prior work found that
3906 people are sensitive to distributional properties when generalizing (Carvalho et al.,
3907 2021), but it is not clear if this will replicate with descriptive cues such as in
3908 the experiments in this chapter.

3909 6.4.2 Practical implications

3910 The current work can contribute to managerial decision making by suggesting
3911 insights into how managers make better decisions when using case studies and
3912 statistical information. Managers of large companies are often in a difficult position;
3913 they have incomplete information and an uncertain environment. Despite this,
3914 different biases and responses to those biases can be anticipated for different levels
3915 of uncertainty. For instance, a manager may be presented with both a convincing
3916 case study that suggests a certain course of action, and aggregated data. The
3917 manager needs to be able to weigh the evidence accordingly.

3918 The work in this chapter suggests that there are three elements to consider:
3919 1. the quality of the aggregated data (determined by factors such as the sample
3920 size), 2. the relative similarity of the cases in the data pool to the target situation,
3921 and 3. the similarity of the anecdote to the target. For instance, if the anecdote is
3922 relevantly similar to the target situation, and it is significantly more similar than
3923 the rest of the cases in the data set, then it should have more weight than an
3924 anecdote that comes from a pool of cases that are all equally similar to the target.

6. Anecdote similarity moderates anecdotal bias in capital allocation

3925 Lovallo et al. (2012) found that similarity judgements increase prediction accuracy
3926 beyond a simple regression model. Taking into account the relative similarity to
3927 other cases is likely to further increase predictive validity.

3928 In a situation in which aggregated data are not available, however, managers
3929 should rely more on anecdotes that are more similar in causal structure. That is,
3930 they should be wary of merely using the surface similarity to make inferences, and
3931 instead consider the underlying relational structures. The present data suggest
3932 that laypeople can do this to an extent, with participants not being completely
3933 swayed by the mere similarity of the type of business project. However, future
3934 research should investigate this further to better understand the boundaries of
3935 people's analogical reasoning in capital allocation decisions.

6. Anecdote similarity moderates anecdotal bias in capital allocation

4040

4041

4042 This thesis investigated the psychology of capital allocation decisions. The
4043 influence of psychological factors on such decisions has not been sufficiently consid-
4044 ered in the literature despite their importance to the performance of hierarchical
4045 organisations. This discrepancy is likely due to a greater focus of the role of
4046 organisational influences on firm performance in the management literature. The
4047 thesis did not investigate expertise effects, but instead focused largely on participants
4048 without management experience. This allowed a study of the specific cognitive
4049 processes without the potential confound of experience. Though, it is also worth
4050 noting that, in the one case where the work examined people with management
4051 experience, the pattern of results was largely the same as with naive participants.

7. Discussion

4052 Each of the empirical chapters investigated distinct but related processes that are
4053 relevant to the capital allocation process. These chapters investigated whether
4054 people were able to account for the benefits of aggregation when considering
4055 multiple projects (Chapter 2), the influence of project feature alignability and
4056 metric variance when comparing projects directly (Chapter 4), and the influence
4057 of project anecdote similarity when the anecdote conflicts with statistical evidence
4058 (Chapter 6). Section 7.1 will first summarise the results of the empirical chapters, and
4059 Sections 7.2 and 7.3 will then discuss their theoretical and practical implications,
4060 respectively. Section 7.4 will conclude the thesis.

4061 7.1 Summary of results

4062 Chapter 2 investigated participants' choice of risky business projects, when these
4063 are displayed sequentially and without feedback in between decisions. This design
4064 modelled the real-life situation that managers face in hierarchical organisations:
4065 an evaluation of a set of separate business project proposals over time with no
4066 immediate indication of the performance of those projects. Aggregating a portfolio
4067 of such projects is likely to show a lower chance of potential loss overall than might
4068 be originally assumed. The results from this chapter showed that people not only
4069 did not do this spontaneously, but also were not facilitated by manipulations that
4070 encouraged grouping choices together as a portfolio. People only seemed to recognise
4071 the benefits of aggregation when they were presented with an outcome probability
4072 distribution of the aggregated set of projects. There was no strong evidence that
4073 more subtle manipulations aimed at encouraging aggregation worked. Specifically,
4074 presenting projects together, specifying the total number of projects, and presenting
4075 projects that were all from the same industry did not reliably encourage aggregation.

4076 Chapter 4 investigated capital allocation when projects were evaluated jointly
4077 and capital was allocated as a proportion of the budget, rather than a binary choice.
4078 The main manipulation was whether all the project attributes were alignable, or only
4079 the abstract financial metric (NPV) was alignable. NPV was also manipulated to be

7. Discussion

4080 considered as either a reliable metric or not. This information was expressed either
4081 as explicit verbal instruction or as numerical ranges. The results showed that when
4082 reliability information was presented verbally, participants used it appropriately
4083 when all project attributes were completely alignable. That is, they used it when it
4084 was reliable and used the intrinsic project features when it was unreliable. When
4085 only NPV was alignable, participants relied on it almost exclusively. However,
4086 when reliability information was presented numerically, there was no moderation
4087 of allocation based on the ranges—participants used NPV even when they had
4088 an opportunity to use the intrinsic features of the project. Overall, however,
4089 participants tended to rely on NPV more when projects were low in alignment
4090 than when they were high in alignment.

4091 Chapter 6 investigated the effect of anecdote similarity on allocations when the
4092 anecdote conflicted with the statistical data. Participants were asked to allocate
4093 a hypothetical budget between two projects. One of the projects (the target
4094 project) was clearly superior in terms of the provided statistical measures, but
4095 some of the participants also saw a description of a project with a conflicting
4096 outcome (the anecdotal project). This anecdotal project was always in the same
4097 industry as the target project. The anecdote description, however, either contained
4098 substantive connections to the target or not. Further, the anecdote conflicted
4099 with the statistical measures because it was either successful (positive anecdote) or
4100 unsuccessful (negative anecdote). The results showed that participants' decisions
4101 were influenced by anecdotes only when they believed that they were actually relevant
4102 to the target project. Further, they still incorporated the statistical measures into
4103 their decision. This was found for both positive and negative anecdotes. Further,
4104 participants were given information about the way that the anecdotes were sampled
4105 that suggested that the statistical information should have been used in all cases.
4106 Participants did not use this information in their decisions and still showed an
4107 anecdotal bias effect. Therefore, people seem to appropriately moderate their
4108 use of anecdotes based on the anecdotes' relevance, but do not understand the
4109 implications of certain statistical concepts.

7. Discussion

4110 Together, these results show the bounds of people's decision-making capability
4111 in capital allocation. The participants in these experiments in general behaved
4112 rationally but struggled to incorporate certain statistical concepts into their decisions.
4113 Further, when confronted with multi-attribute choice, participants tended to allocate
4114 capital using a trade-off strategy. This was seen in the conflict between intrinsic
4115 project attributes and NPV in Chapter 4 and the conflict between the anecdotal
4116 and statistical evidence in Chapter 6. Participants were able to moderate their
4117 allocations when the moderating factors were sufficiently clear (as in the verbal
4118 reliability condition in Chapter 4). However, participants struggled to do this when
4119 the moderating factor involved using a relatively basic statistical concept. Each
4120 empirical chapter included such a concept: risk aggregation in Chapter 2, metric
4121 variance in Chapter 4, and sample distribution in Chapter 6. The aggregated
4122 distribution in Chapter 2 and the verbal reliability manipulation in Chapter 4
4123 showed that a formal understanding of such concepts is not always necessary if
4124 they are expressed explicitly.

4125 The statistical concepts used in these studies are all likely accessible for people
4126 without much formal mathematical knowledge. A basic concept of risk aggregation
4127 is clearly available to laypeople as seen in the responses to multi-play gambles
4128 (e.g., one vs. 100 gambles). Further, people certainly have a basic understanding of
4129 numerical ranges and that a wider range means more spread. Despite likely having
4130 this understanding, participants in the above experiments were unable to use it in
4131 the decisions. Similarly, other work has shown that generalisations are sensitive to
4132 sampling (Carvalho et al., 2021). Therefore, it is unlikely that the people in the
4133 thesis experiments simply lacked any understanding of these statistical concepts
4134 or (at least sensitivity to this kind of information). Instead there appear to be
4135 important contextual factors that critically support or prevent people from showing
4136 their intuitive understanding. Unfortunately, the methods used in this thesis more
4137 closely resemble real decisions managers make, than the prior research that showed
4138 people do think with these kinds of statistical concepts. Further, it is not clear that
4139 these effects will simply disappear with just more maths knowledge and business

7. Discussion

⁴¹⁴⁰ experience. Previous work showed that expertise does not always remove biases
⁴¹⁴¹ and in some cases it seems to augment such effects (e.g., Haigh & List, 2005).

⁴¹⁴² 7.2 Theoretical implications

⁴¹⁴³ The main theoretical contribution of this thesis is the addition of evidence
⁴¹⁴⁴ that further specifies the conditions under which people make rational decisions
⁴¹⁴⁵ in capital allocation scenarios. People made good decisions most of the time, but
⁴¹⁴⁶ sometimes do not take into account important moderating factors in their decisions.
⁴¹⁴⁷ Amos Tversky explained in his response to Cohen (1981, p. 355) that the work
⁴¹⁴⁸ on heuristics and biases “portrayed people as fallible, not irrational.” That is,
⁴¹⁴⁹ people are not constantly making mistakes, but often behave rationally, largely
⁴¹⁵⁰ due to adaptive heuristics. However, sometimes shortcuts that are usually helpful
⁴¹⁵¹ can fail. Studying such biases is similar to the way that optical illusions help
⁴¹⁵² understand the visual system. In both cases, these are systems that most of the
⁴¹⁵³ time function properly, but sometimes reveal deficits.

⁴¹⁵⁴ Similarly, Simon (1955) identified human rationality as *bounded*, meaning that
⁴¹⁵⁵ people’s cognitive processes are limited. The main aim of the thesis was to contribute
⁴¹⁵⁶ evidence for the ways that capital allocation decisions are bounded. To this end,
⁴¹⁵⁷ in each experiment, participants were given capital allocation scenarios alongside
⁴¹⁵⁸ both cues that describe their options and cues that frame the options in different
⁴¹⁵⁹ ways. Identifying which cues were used by participants in their decisions, which
⁴¹⁶⁰ cues were ignored, and which cues were integrated allowed to specify the bounds
⁴¹⁶¹ of people’s cognitive capacity in these decisions. The experiments showed that
⁴¹⁶² people struggle to use certain statistical concepts in their decisions, but that they
⁴¹⁶³ are also capable of making nuanced trade-offs and can be assisted by decision aides.
⁴¹⁶⁴ Understanding how decision-making in capital allocation is constrained and biased
⁴¹⁶⁵ is important in order to improve decision-making. Even if decisions are largely
⁴¹⁶⁶ consistent with normative concepts, falling prey to the biases identified in this
⁴¹⁶⁷ thesis can have severe consequences for organisations.

7. Discussion

4168 7.2.1 Statistical concepts

4169 Chapter 2 presented participants with a capital allocation situation in which an
4170 understanding of risk aggregation would have led to beneficial outcomes. Investing
4171 in all the hypothetical projects would have led to a much higher chance of gaining
4172 money than losing any. Each choice bracketing manipulation provided a hint of
4173 the possibility of combining the choices in this way. However, participants did not
4174 need to compute the aggregated value of the prospects themselves. An intuitive
4175 understanding of aggregation involved considering that some of the gambles will
4176 pay-off and make up for those that lost. However, this was not seen, with only
4177 weak evidence that people were influenced by the more subtle choice bracketing
4178 manipulations. Instead, people only seemed to respond to the concept of aggregation
4179 when it was explicitly showcased. Showing people a distribution of the outcome
4180 probabilities explicitly visualised the extent to which an aggregation of the risks
4181 can lead to an incredibly low chance of loss.

4182 In Chapter 4, the NPVs that participants saw were critical to the allocation
4183 task. In the low alignment condition, NPV was the only alignable attribute in the
4184 comparison. In the high alignment condition, however, NPV was in competition
4185 with the intrinsic project feature values. An understanding of how to use numerical
4186 variance would have allowed participants to moderate their allocations according to
4187 the implied reliability of the comparison metric. In the low alignment condition,
4188 NPV was the only easy way to compare across projects, so it was a more useful cue
4189 than the rest of the non-alignable values. However, in the high alignment condition,
4190 the extent of numerical variance associated with each NPV could have been used to
4191 determine NPV reliability. There were two ways to do this: 1. noticing that in the
4192 low numerical reliability condition the ranges were all overlapping, and 2. noticing
4193 the difference in the width of the ranges between the two within-subjects reliability
4194 amount conditions. By doing this, participants would have then been able to know
4195 to (in the high alignment condition) use NPV when ranges were narrow and use
4196 the intrinsic values more or exclusively when ranges were wider and overlapping.

7. Discussion

4197 Participants were able to do this sort of moderated allocation when reliability was
4198 expressed explicitly as words, but not when it was expressed numerically.

4199 In Chapter 6, participants did not make use of descriptive information about
4200 the anecdote sample distribution. As in Chapter 4, participants were confronted
4201 with a conflict of cues: statistical information vs. a potentially relevant anecdote.
4202 Regardless of the similarity manipulation, a consideration of the sample from which
4203 the anecdote was sampled should have informed how the anecdote was used. Imagine
4204 a distribution that represents the similarity of all the individual projects in the
4205 sample. That is, the x-axis represents the similarity to the target project and the
4206 y-axis is the frequency of projects that represent each level of similarity. Even if
4207 the sampled anecdote appears very relevant to the target project, if the underlying
4208 distribution of the sample is highly negatively skewed, such that most projects in
4209 the sample are equivalently similar to the target, then the sampled anecdote is not
4210 necessarily more informative than the aggregated measure. On the other hand, if the
4211 underlying distribution was positively skewed, normally distributed, or even uniform,
4212 then the fact that the sampled anecdote appears highly relevant to the target project
4213 may actually mean that it is more informative than the aggregated measure. Prior
4214 work shows that people can reason about distributions effectively when experiencing
4215 the sampling directly (e.g., Carvalho et al., 2021; Hertwig et al., 2004). Chapter 6
4216 shows that people struggle to use this information when it is described verbally.

4217 While people struggled to understand and use certain statistical concepts they
4218 still seemed to be able to integrate multiple cues and create trade-offs. As discussed
4219 in Chapter 5, both Chapters 4 and 6 provided participants with more than one
4220 cue to use for project evaluation. In Chapter 4, people seemed to strike a trade-off
4221 between NPV and the intrinsic project features as opposed to choosing one or
4222 the other with a consistent strategy. In Chapter 6, the anecdotal and statistical
4223 evidence provided conflicting cues for each target project. However, participants
4224 allocated as if both the anecdotes and statistics had some relevance. Similar to the
4225 above, participants appeared to integrate the influence of these two cues, as opposed
4226 to picking a consistent evidence reliance strategy for their allocation decisions.

7. Discussion

4227 These findings might be explained through satisficing (Simon, 1955) or a constraint
4228 satisfaction model (e.g., Glöckner et al., 2014). Future research can test these
4229 explanations, as well as further clarify to what extent constructs such as need for
4230 cognition or mathematical skill may explain individual differences.

4231 7.2.2 Decision aides

4232 While trade-offs allow people to integrate multiple cues, decision aides allow
4233 people to use statistical concepts for more nuanced moderation. Chapter 2 found
4234 that people's understanding of risk aggregation was facilitated when the mathe-
4235 matical work was done for them and the aggregated values were displayed visually
4236 as a distribution. However, a follow-up experiment to Chapter 4 (detailed in
4237 Appendix B.7) found that even explicit instructions sometimes do not work. That
4238 is, even explaining the way that ranges can be used as reliability information
4239 and telling participants how to implement this in the capital allocation task did
4240 not facilitate proper use of ranges.

4241 Future work should investigate the impact of visualisation on people's use of
4242 variance information in these situations. Much work has investigated visualising
4243 uncertainty information (Bostrom et al., 2008; Brodlie et al., 2012; T. J. Davis &
4244 Keller, 1997; Johnson & Sanderson, 2003; Kinkeldey et al., 2017; Kox, 2018; Lapinski,
4245 Lipkus & Hollands, 1999; Lipkus, 2007; MacEachren, 1992; Padilla et al.,
4246 2018; Pang et al., 1997; Potter et al., 2012; Ristovski et al., 2014; Spiegelhalter et al.,
4247 2011; Torsney-Weir et al., 2015). A Hypothetical Outcome Plot (HOP; Hullman
4248 et al., 2015; Kale et al., 2019) expresses variance information as dynamic plots and
4249 is one method that is likely to be beneficial to people's understanding of ranges
4250 as used in this thesis. Visualisation could also apply to the work in Chapter 6.
4251 Using a visual array as in Jaramillo et al. (2019) is likely to facilitate people's
4252 understanding of the importance of statistical evidence over anecdotes. However,
4253 an additional visualisation of the distribution of the underlying similarity to the
4254 target might also be necessary to facilitate understanding of the relevance of the

7. Discussion

4255 sample distribution. Ultimately, visualisations of the effects of certain statistical
4256 concepts might be necessary for people to use them appropriately.

4257 7.2.3 How bounded is bounded rationality?

4258 The boundary between the cues that participants were able to use and the
4259 statistical concepts that they did not use is unclear. That is, the cues that they
4260 were able to use were not trivial, and the concepts that they were not able to use are
4261 relatively basic. For instance, the finding in Chapter 6 that people were able to use
4262 relevance information to guide their allocations shows an ability to moderate choice
4263 based on quite specific information. On the other hand, the statistical concepts that
4264 participants ignored in each empirical chapter are all relatively intuitive. While
4265 concepts of aggregation, variance, and sample distribution are typically studied at
4266 a tertiary level, they can be understood when acted out or experienced.

4267 Clark and Karmilff-Smith (1993) proposed a distinction between two levels of
4268 representing knowledge. At the *implicit* level an individual can only make use
4269 of a certain system of knowledge, while it is only at the *explicit* level that they
4270 develop insight into that system. For instance, young children can use closed class
4271 words such as “the” or “to,” but only identify them as words later in development.
4272 Further, children’s play often implicitly contains many mathematical concepts,
4273 despite the children’s struggle to explicitly reason with the exact same concepts in
4274 more formal problem-solving (Sarama and Clements (2009)). Adults may have a
4275 similar distinction in knowledge representation. Concepts that can be used when
4276 experienced directly, such as in risky choice from experience, are not represented in
4277 a way that they can be used when presented descriptively, such as in risky choice
4278 from description. This kind of distinction may explain why participants in the thesis
4279 experiments failed to use concepts that have been shown to be accessible to laypeople.

4280 7.2.4 Expertise effects

4281 Future research should also investigate the potential expertise effects that may
4282 influence the findings of the thesis. This is important because of the potential

7. Discussion

downstream effects of biased managerial decision-making. For instance, it is unclear to what extent psychological factors such as the ones discussed in this thesis may account for the finding that undiversified firms often perform better than diversified firms. On the one hand, business professionals tend to work with numbers, so the effects found in this thesis may be less pronounced for them. For instance, Smith and Kida (1991) reviewed the heuristics and biases literature and concluded that certain cognitive biases are not as strong for accounting professionals as they are for naive participants.

On the other hand, these effects may actually be stronger in managers. For instance, Haigh and List (2005) found that professional traders show more myopic loss aversion than students. Chapter 2 showed that people tend to consider risky choices one at a time and therefore tend to be more risk averse to a set of projects than they would be if the risks were aggregated. Managers might be even more risk averse in these situations because of the increased stakes for their jobs. Lovallo et al. (2020) discussed the ways in which managers tend to have a blind spot for such project evaluations: they aggregate their personal stock market portfolio, but not their intra-firm project portfolio.

Chapter 4 found evidence of variance neglect for both laypeople and Masters of Management students. Further, in the case of the work in Chapter 6, it is possible that business managers prefer anecdotal cases to inform their decisions because of their higher salience, compared to statistical data. Managers are also more likely to feel as if the situation is relevant to them, which according to Freling et al. (2020) would suggest more anecdotal bias.

7.3 Practical implications

The findings of this thesis have a number of potential implications for managerial decision-making. Despite the uncertainty about potential expertise effects, this section assumes that the findings of the thesis generalise to experienced managers, if not in degree, at least qualitatively. Management researchers have suggested ways of

7. Discussion

4311 overcoming psychological biases in managerial decision-making ever since such biases
4312 were identified. Many practitioner-oriented papers have used the findings of the
4313 judgement and uncertainty literature both to explain managerial decision-making
4314 processes and to suggest ways of reducing bias (Courtney et al., 1997; Courtney
4315 et al., 2013; Hall et al., 2012; Koller et al., 2012; Lovallo & Sibony, 2014; Sibony
4316 et al., 2017), with only some specifically focused on capital allocation decisions
4317 (Birshan et al., 2013). This section will review some of the implications the findings
4318 of this thesis may have on both organisational policies and manager decision-making.

4319 The findings of Chapter 2 show that the way that the framing of business project
4320 proposals important for the way that people perceive their risk. Specifically, in
4321 order to better account for the risks of business projects it is important to 1. make
4322 it easier for managers to group projects together, and 2. aggregate a portfolio of
4323 projects for them. This suggests implementing organisational changes that will
4324 facilitate the capital allocation process. For instance, Lovallo et al. (2020) suggested
4325 that companies change the frequency that they evaluate projects to better allow
4326 for an aggregation of the projects. Doing this will enable an explicit computation
4327 of the aggregated values and therefore a visualisation of the outcome probability
4328 distribution. Such a process could facilitate aggregation without a need to rely on
4329 managers' intuition during sequential project evaluation decisions.

4330 One implication of Chapter 4 is that it is important to expose the variance
4331 that underlies abstract financial measures. Further, translating such numerical
4332 variance estimates into clear verbal information would help facilitate managers'
4333 understanding and implementation of such estimates. Organisational changes could
4334 include reducing diversification so that there is less reliance on abstract metrics.
4335 This would allow for more of a comparison between alignable project attributes,
4336 potentially reducing forecast error. Koller et al. (2017) found that companies
4337 with more similar business units report faster growth and greater profitability
4338 than competitors, compared to companies with dissimilar business units. Further,
4339 companies can also work to develop better metrics and establish norms about how
4340 much to discount a metric given its underlying variance.

7. Discussion

4341 The main implication of Chapter 6 is that managers should pay attention to
4342 the way that they compare target projects to other cases. It is important to collect
4343 prior cases that are relevant, and to have as many such cases as possible. Ideally,
4344 each such prior case should be weighed by similarity (Lovallo et al., 2012). If this
4345 is done, the prior distribution of the similarity of the sample would be taken into
4346 account when computing subsequent aggregation. When identifying such similarity
4347 ratings, it is important to focus on relevant underlying structure. This would
4348 reduce any erroneous connections to cases that only have a mere surface similarity.
4349 This distinction is also relevant in a situation in which only one prior case can be
4350 found. Research on analogy shows that analogical comparison helps expose the
4351 underlying relational structure between objects (e.g., Kurtz et al., 2013; Markman
4352 & Gentner, 1993). Therefore, managers should take care to first identify such
4353 relational structures first before making subsequent inferences.

4354 Addressing these psychological effects will help eliminate some of the biases
4355 in the capital allocation process, but will not address other related biases. For
4356 instance, the above effects all involve decisions that require an evaluation of
4357 financial forecast estimates such as future cash flows and the related uncertainty.
4358 Therefore, a further source of error could arise from the initial estimation of
4359 these probability and cash flow values. For instance, such estimates could be
4360 influenced by optimism or confidence biases. These biases, however, can in turn
4361 be addressed (Flyvbjerg et al., 2018).

4362 7.4 Conclusion

4363 Capital allocation decisions can be consequential for large organisations. This
4364 thesis tested the conditions under which people behave rationally or are fallible
4365 when allocating capital. The experiments found that people struggle to incorporate
4366 concepts such as risk aggregation, estimate variance, and sample distribution into
4367 their decisions. People only seemed to be able to do this when the concept was
4368 expressed visually very explicitly. However, when there were multiple cues for

7. Discussion

⁴³⁶⁹ choice evaluation, the results also showed that people were capable of integrating
⁴³⁷⁰ conflicting information in their decisions. Identifying such cognitive bounds helps
⁴³⁷¹ to better understand how people evaluate multiple choices and helps future research
⁴³⁷² develop methods to facilitate better decisions.

4517

4518 This appendix contains supplementary materials and analyses for the two
4519 experiments reported in Chapter 2. In addition, it also report two experiments
4520 that were conducted to follow-up the findings in Experiments 1 and 2. Both
4521 follow-up experiments tested project choice as in the first two experiments, but
4522 Experiment 3 further investigated the effect of similarity, and Experiment 4 further
4523 investigated the effect of awareness.

4524

 All four experiments featured probability outcome distributions. These were

A. Chapter 2 appendix

Imagine that you are an executive in a large company composed of many individual businesses.

You will see various projects from these businesses and have to decide whether you would like to invest in them.

Imagine that making good investment decisions will result in you receiving a generous bonus and a potential promotion, and that doing poorly will result in you receiving a large pay cut and a potential demotion.

We want to know what choices you would actually make in these scenarios.

4525 Poisson binomial distributions that were calculated using the R package `poibin`,
4526 which uses calculations described in Hong (2013).

4527 **A.1 Experiment 1**

4528 **A.1.1 Method**

4529 **A.1.1.1 Materials**

4530 **A.1.1.1.1 Instructions** Participants were shown the instructions in Figure A.1.

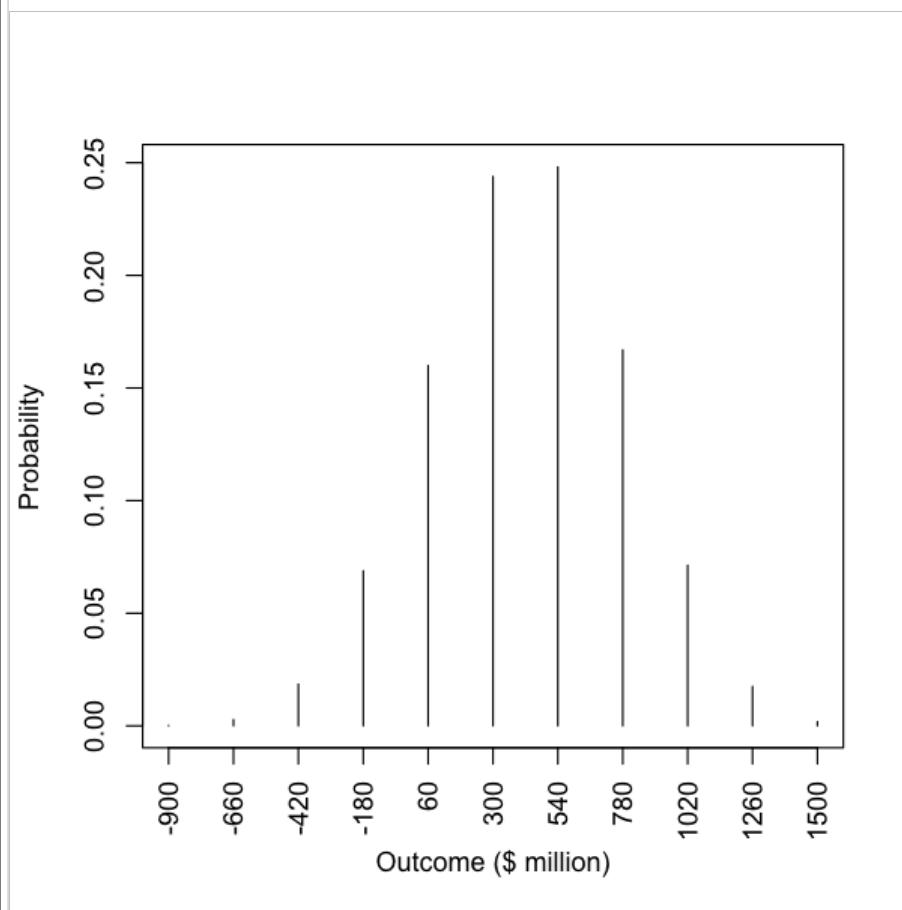

4531 **A.1.1.1.2 Outcome distribution decision** Figure A.2 shows the outcome
4532 distribution display that participants saw in Experiment 1.

4533 **A.1.1.1.3 Follow-up gambles**

4534 **Negative EV gambles** It was important to make sure that participants
4535 were generally making decisions that were in line with EV theory and that the
4536 sample was not abnormally risk tolerant. As such, participants saw two project
4537 decisions that had a negative EV. Out of the 396 negative EV gambles included
4538 (two per participant), all but four were rejected.

A. Chapter 2 appendix

Below is the distribution of final outcomes after the last 10 investments you just saw. That is, each possible outcome is shown on the x-axis, and the probability of each outcome is shown on the y-axis. Regardless of what you decided previously, would you invest in all 10 of those investments, given the below distribution?

*

Yes No

Figure A.2: The outcome distribution of the 10 gambles used in Experiment 1. Border added for clarity.

A. Chapter 2 appendix

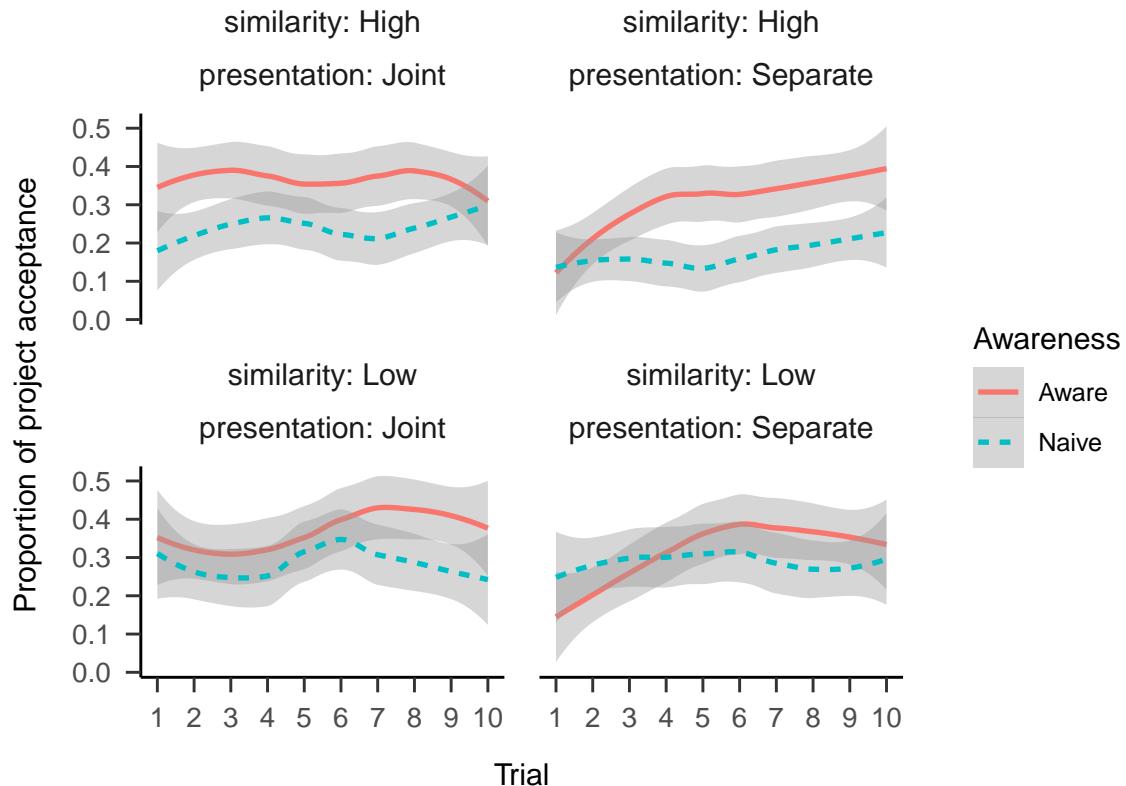

Figure A.3: Proportion of project acceptance by trial, similarity, awareness, and presentation conditions. LOESS is used for smoothing over trials, and the shading represents 95% confidence intervals.

4539 **Samuelson (1963) gambles** Participants saw the original Samuelson (1963)
 4540 gamble, were asked whether they would accept 10 of that gamble, and whether they
 4541 would accept those 10 given the associated outcome distribution. They then saw
 4542 the same three questions, but using outcome magnitudes that were similar to the
 4543 ones in the risky investment task. That is, \$100 million instead of \$100.

4544 **Redelmeier and Tversky (1992) gambles** Participants saw the same three
 4545 types of gambles (single, 10, and aggregated), but with the values from the gambles
 4546 that were used by Redelmeier and Tversky (1992).

4547 A.1.2 Results

4548 A.1.2.1 Trial-by-trial analysis

4549 Figure A.3 shows proportions of project acceptance across all conditions and tri-
 4550 als.

A. Chapter 2 appendix

A.1.2.2 Outcome distribution

A paired-samples t-test was conducted to compare participants' decision to invest in the 10 projects while seeing an aggregated distribution, and their decisions to invest in the projects individually, without the distribution. Participants invested in the 10 projects more when seeing the distribution both in the separate presentation phase, $t(197) = 5.48, p < .001, d_z = 0.50, 95\% \text{ CI } [0.31, 0.68]$; and in the joint presentation phase, $t(197) = 4.17, p < .001, d_z = 0.37, 95\% \text{ CI } [0.19, 0.56]$.

However, it was subsequently discovered that the code that generated this distribution mistakenly flipped the outcome values. This means that although it appeared from the distribution that the probability of loss was 0.09, the actual probability of loss of the underlying values given the correct distribution was 0.26. As such, even though Experiment 1 found an effect of distribution, it was unclear if the effect was driven by participants actually accurately assessing the riskiness of the individual gambles, and therefore showing a difference between the isolated and aggregated gambles in a normative way.

A.2 Experiment 2

A.2.1 Method

A.2.1.1 Participants

A.2.1.1.1 Power analysis The power analysis was conducted using the `pwr` package (Champely, 2020), based on the presentation effect size from Experiment 1, since it was the smallest effect. The analysis suggested that a minimum sample size of 164 ($41 \cdot 4$) was required for the presentation effect with an expected power of at least 80%.

A.2.1.2 Materials

A.2.1.2.1 Follow-up Figure A.4 shows the project number question. The maximum value that they could enter was set to 20. Figures A.5 and A.6 ask participants whether they are willing to take all or none of the projects; and how

A. Chapter 2 appendix

In total, how many projects did you just see?

projects

Continue

Figure A.4: Experiment 2 project number question. Border added for clarity.

many projects would they choose if they could pick randomly (maximum value was set to 20). Those in the distribution absent condition were asked the same questions, but without the distribution and its explanation.

A.2.2 Results

A.2.2.1 Follow-up

A.2.2.1.1 Project number Participants were asked how many projects they thought they saw. Figure A.7 shows that overall people correctly estimated the number of projects, with more accuracy for those in the aware condition.

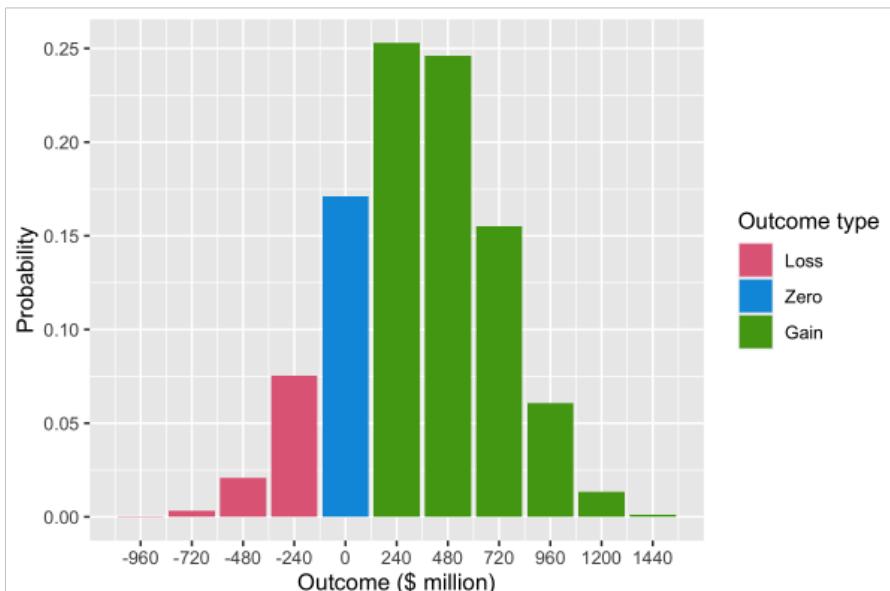

A.2.2.1.2 Portfolio choice - binary Participants were then asked if they would rather invest in all or none of the projects. As Figure A.8 shows, the difference between presentation conditions was not significant, $\hat{\beta} = 0.15$, 95% CI $[-0.29, 0.60]$, $z = 0.67$, $p = .500$. The awareness effect was also not significant, $\hat{\beta} = 0.28$, 95% CI $[-0.17, 0.72]$, $z = 1.21$, $p = .225$. However, those that saw a distribution chose to invest in all 10 projects significantly more (71.43%) than those that did not see a distribution (36.59%), .

A.2.2.1.3 Portfolio choice - number Subsequently, participants were asked how many projects they would invest in out of the 10 that they saw. As Figure A.9 shows, the difference between presentation conditions was not significant, $d_s = 0.08$, 95% CI $[-0.35, 0.52]$, $t(80) = 0.38$, $p = .706$. The awareness effect was also not significant, $d_s = 0.09$, 95% CI $[-0.34, 0.53]$, $t(79) = 0.42$, $p = .678$. However, those that saw a distribution chose to invest in significantly more projects than those that did not see a distribution, $d_s = 0.60$, 95% CI $[0.15, 1.03]$, $t(81) = 2.70$, $p = .009$.

A. Chapter 2 appendix

Below is the probability distribution of final outcomes if all projects were chosen.

The numbers on the x-axis (labelled 'Outcome') represent the final amounts of money possible if you chose to invest in all the projects. The numbers on the y-axis (labelled 'Probability') represent the likelihoods of each of the possible outcomes. Negative final outcomes (losses) are shown in red, positive final outcomes (gains) are shown in green, and a final outcome of zero (no loss or gain) is shown in blue.

Indicate below whether you would invest in the following:

Consider all the projects you saw. If you had to choose between investing in all of them, or investing in none of them, which would you choose?

Figure A.5: Experiment 2 binary portfolio question. Border added for clarity.

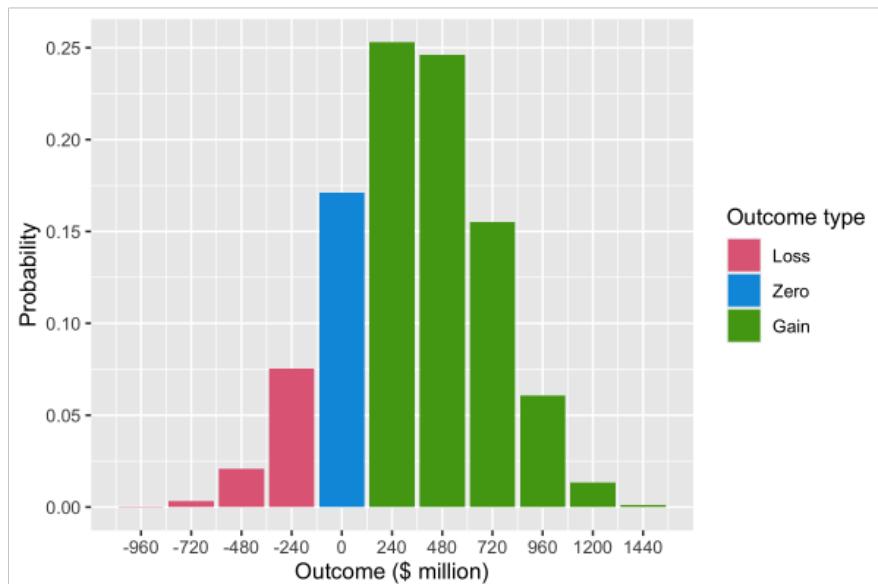

4600 A.2.2.2 Gambles

4601 Figures A.10 and A.11 show that the overall people seemed to prefer gam-
4602 bles with higher probabilities of gain, sometimes regardless of expected value
4603 or value of the gain.

A. Chapter 2 appendix

Below is the probability distribution of final outcomes if all projects were chosen.

The numbers on the x-axis (labelled 'Outcome') represent the final amounts of money possible if you chose to invest in all the projects. The numbers on the y-axis (labelled 'Probability') represent the likelihoods of each of the possible outcomes. Negative final outcomes (losses) are shown in red, positive final outcomes (gains) are shown in green, and a final outcome of zero (no loss or gain) is shown in blue.

Indicate below whether you would invest in the following:

The total number of projects you were shown is 10 . If you could choose to invest in a certain number of those 10 projects, how many would you invest in?

projects

Continue

Figure A.6: Experiment 2 numerical portfolio question. Border added for clarity.

A.3 Experiment 3

Experiment 3 investigated the effect of similarity on project choice. The previous experiments did not counterbalance the project domain when displaying the 10 projects to participants. Experiment 3 used 10 different potential business domains when constructing the project descriptions in order to reduce any potential effect that the specific domain may have on people's choice. Therefore, Experiment 3

A. Chapter 2 appendix

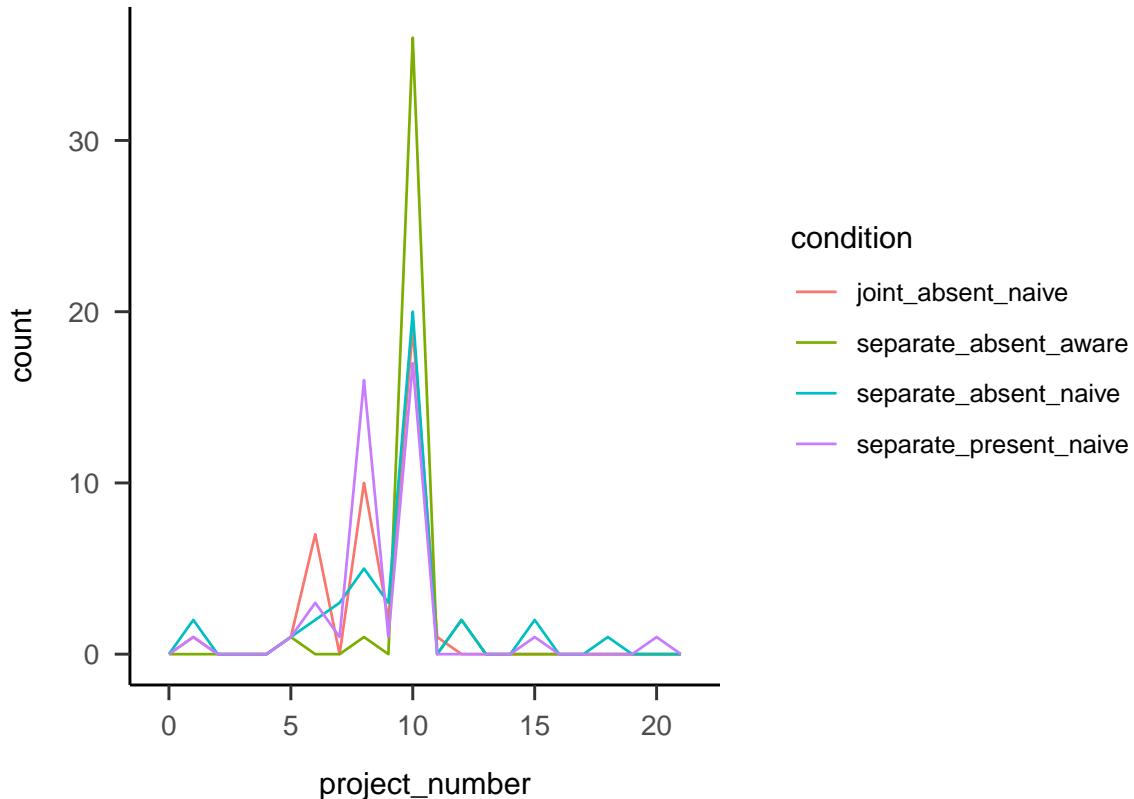

Figure A.7: Number of projects participants reported seeing, by condition.

4610 again tested Hypothesis 2.3.

4611 A.3.1 Method

4612 A.3.1.1 Participants

4613 Two hundred and sixty-six people (127 female) were recruited from the online
4614 recruitment platform Prolific. Participants were compensated at a rate of £5 an
4615 hour. The average age was 39.56 ($SD = 8.77$, $min = 25$, $max = 71$). Participants
4616 reported an average of 5.64 ($SD = 6.45$, $min = 0$, $max = 40$) years of work in a
4617 business setting, and an average of 3.28 ($SD = 4.92$, $min = 0$, $max = 30$) years of
4618 business education. The mean completion time was 9.23 ($SD = 7.2$, $min = 1.41$,
4619 $max = 65.46$) minutes. Table A.1 shows the between-subjects condition allocation.

4620 A.3.1.2 Materials

4621 **A.3.1.2.1 Instructions** Participants were shown the same instructions as in
4622 Experiment 1 (see Section 2.2.1.2.1).

A. Chapter 2 appendix

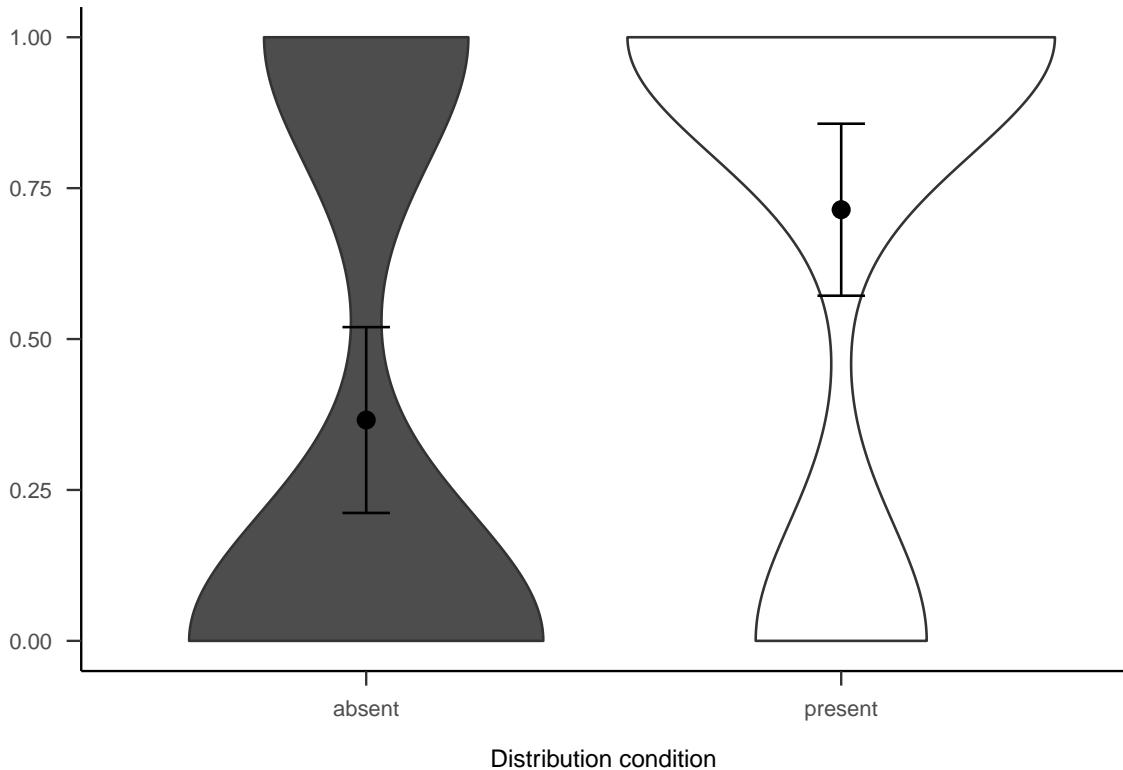

Figure A.8: Mean choice of investing in all 10 projects for the presentation, awareness, and distribution effects. Note, the condition on the left of each effect is the reference condition (separate presentation, naive awareness, distribution absent). As such, it is identical for the three effects.

Table A.1: Experiment 3 group allocation.

Similarity	N
High	133
Low	133
Total	266

A. Chapter 2 appendix

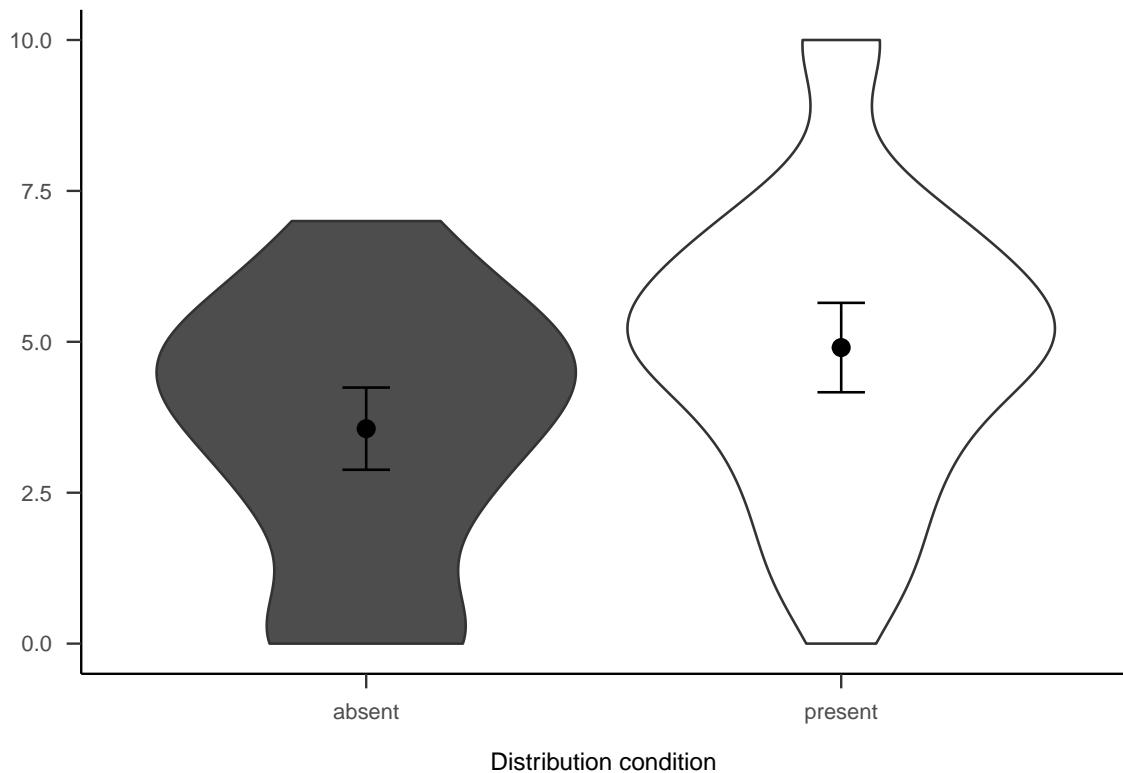

Figure A.9: Mean number of projects chosen in the follow-up for the presentation, awareness, and distribution effects. Note, the condition on the left of each effect is the reference condition (separate presentation, naive awareness, distribution absent). As such, it is identical for the three effects.

4623 **A.3.1.2.2 Risky investment task** Participants saw displays with the same
4624 gamble values as those in Experiment 2 (see Section 2.3.1.2.2), but with some
4625 changes in wording and sentence structure. The gamble information was the same,
4626 but extra prose was added to describe the projects. Further, the order of the
4627 sentences was randomised, so that the descriptions would not appear so similar.
4628 See Figure A.12 for an example.

4629 The similarity manipulation was as in Experiment 1. However, project domain
4630 was varied so that in the high similarity condition participants saw one of ten
4631 project domains.

4632 **A.3.1.2.3 Follow-up** The follow-up questions were similar to those in Experi-
4633 ment 2 (see Section 2.3.1.2.3), except in the portfolio number question participants
4634 were also shown the total number of projects that they saw (10). Further, another

A. Chapter 2 appendix

Indicate below whether you would invest in the following:

To summarise this investment, there is a 30% chance of gaining \$200 million (the forecasted revenue minus the cost amount) and a 70% chance of losing \$40 million. The company would make \$240 million if the forecasted concentration and quality of recoverable hydrocarbons at the site eventuates. The estimate for the anticipated chance of gain is based on a geological and seismic study of the site, and an analysis of previous similar sites. Refinera is a business in your company that proposes to construct an oil well project. Specifically, they want to establish an exploration site at an onshore location in Houston, US in order to see if the hydrocarbon supply is sufficient to establish a more permanent well. Refinera's research team has been investigating a possible site in an as yet unexplored area. Due to the location and size of the site, and consultant fees (e.g., geologists), they forecast the entire project to cost \$40 million (the loss amount).*

Yes

No

At the begining of the experiment, before you saw any projects, how many projects did you expect to see?

project(s)

Figure A.13: Experiment 3 project expectation question. Border added for clarity.

4635 question was added, asking how many projects participants were expecting to see
4636 at the beginning of the experiment (see Figure A.13).

4637 **A.3.1.3 Procedure**

4638 Participants read the instructions and completed the risky investment task in
4639 their respective conditions. After seeing the individual projects, participants were
4640 then asked the four follow-up questions.

A. Chapter 2 appendix

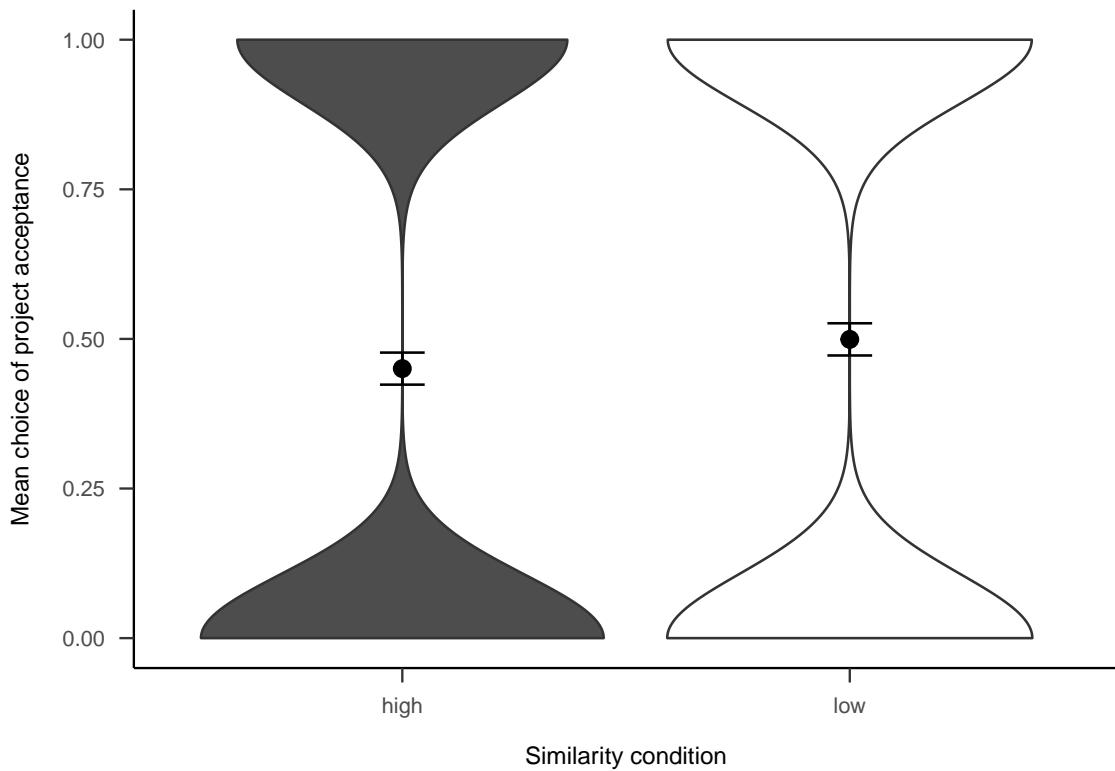

Figure A.14: Mean project acceptance for the similarity effect.

A.3.2 Results

A.3.2.1 Project investment

The project investment data were analysed as in Experiment 2 (see Section 2.3.2). Figures A.14 and A.15 show the choice and proportion data, respectively. The difference between similarity conditions was not significant, both in the logistic regression $b = 0.00$, 95% CI $[-0.18, 0.17]$, $z = -0.04$, $p = .966$, and in the t-test, $d_s = -0.21$, 95% CI $[-0.45, 0.03]$, $t(264) = -1.69$, $p = .093$.

Further, Figure A.16 shows the choice data as a function of the order of the project in the sequence. As Table A.2 shows, there were no main effects or interactions.

A.3.2.2 Follow-up

A.3.2.2.1 Project expectation Participants were asked how many projects they expected to see. As Figure A.17 shows, the difference between similarity conditions was not significant, $d_s = -0.23$, 95% CI $[-0.47, 0.01]$, $t(264) = -1.85$, $p = .065$.

A. Chapter 2 appendix

Term	$\hat{\beta}$	95% CI	z	p
Intercept	0.01	[-0.20, 0.22]	0.07	.944
Similarity1	-0.02	[-0.23, 0.18]	-0.22	.826
Project order	-0.02	[-0.05, 0.01]	-1.52	.127
Similarity1 × Project order	-0.02	[-0.05, 0.01]	-1.07	.284

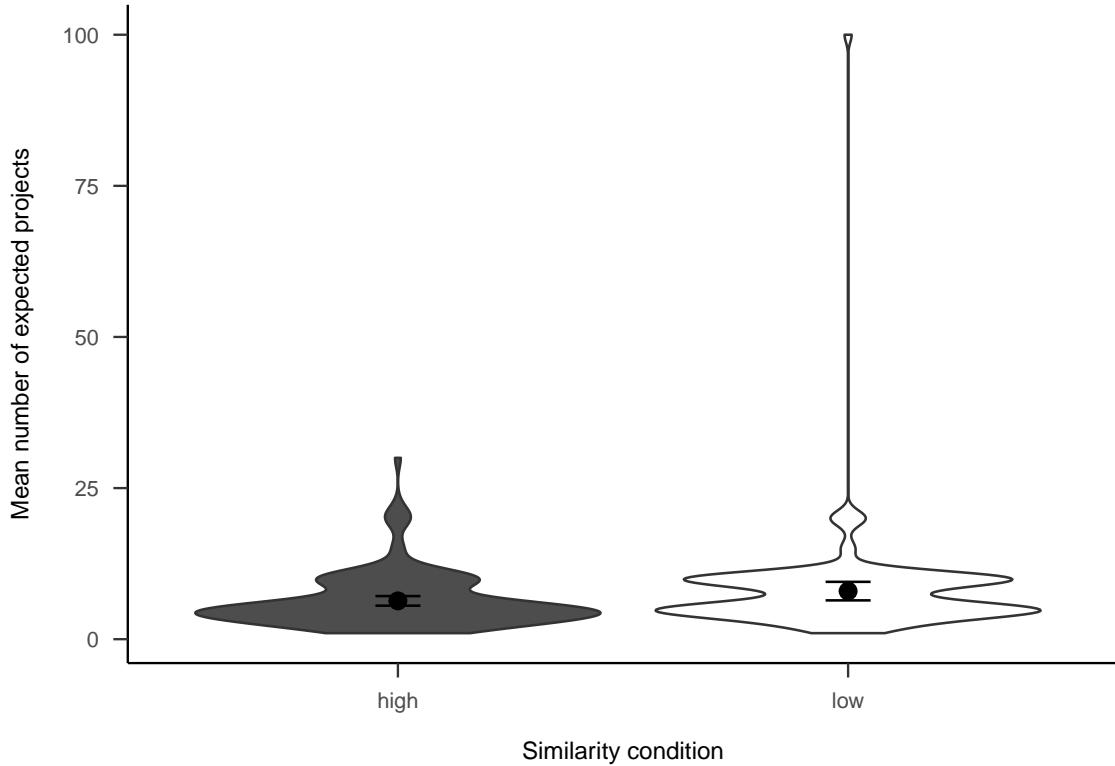

Figure A.17: Number of projects participants expected to see, by similarity.

4654 **A.3.2.2.2 Project number** Participants were asked how many projects they
 4655 thought they saw. Figure A.18 shows that overall people correctly estimate the
 4656 number of projects.

4657 **A.3.2.2.3 Portfolio choice - binary** Participants were then asked if they
 4658 would rather invest in all or none of the projects. As Figure A.19 shows, those in
 4659 the low similarity condition were significantly more likely to want to invest in all
 4660 of the projects, $b = -0.26$, 95% CI $[-0.51, -0.02]$, $z = -2.10$, $p = .036$.

A. Chapter 2 appendix

Figure A.19: Mean choice of investing in all 10 projects for the similarity effect.

A. Chapter 2 appendix

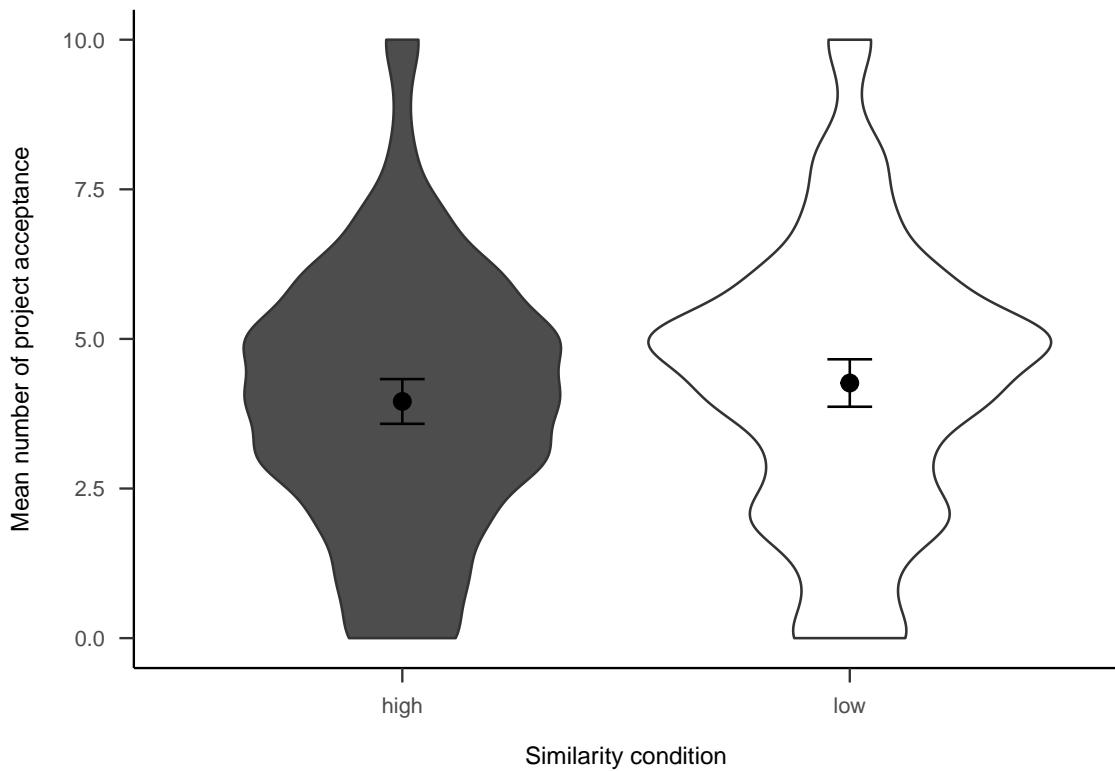

Figure A.20: Mean number of projects chosen in the follow-up for the similarity effect.

⁴⁶⁶¹ **A.3.2.2.4 Portfolio choice - number** Subsequently, participants were asked
⁴⁶⁶² how many projects they would invest in out of the 10 that they saw. As Figure A.20
⁴⁶⁶³ shows, the difference between similarity conditions was not significant, $d_s = -0.14$,
⁴⁶⁶⁴ 95% CI [-0.38, 0.10], $t(264) = -1.12$, $p = .264$.

⁴⁶⁶⁵ **A.3.2.3 Gambles**

⁴⁶⁶⁶ Figures A.21 and A.22 show the overall people seemed to prefer gambles with
⁴⁶⁶⁷ higher probabilities of gain, sometimes regardless of expected value or value of the
⁴⁶⁶⁸ gain.

⁴⁶⁶⁹ **A.3.3 Discussion**

⁴⁶⁷⁰ Experiment 3 found some evidence for the effect of similarity on project choice,
⁴⁶⁷¹ but it was in the opposite direction to the one hypothesised. Specifically, the results
⁴⁶⁷² showed that when considering projects individually, participants' risk aversion did

A. Chapter 2 appendix

Figure A.22: Mean project acceptance for the gambles' expected value, positive probability, and positive outcome.

A. Chapter 2 appendix

4673 not differ between similarity conditions, but when offered a portfolio of the projects,
4674 those that saw the dissimilar projects were more likely to invest.

4675 These results provide evidence for the naive diversification account expressed
4676 above (see Section 2.2.3.3). Specifically, participants may really be naively diver-
4677 sifying, but only when they are explicitly given an opportunity to do so. This
4678 is similar to the multi-play effects because the question itself provides a sort of
4679 choice bracketing. That is, the gambles are grouped together as a portfolio by the
4680 question. Together, this suggests that people are not naively aggregating when
4681 viewing gambles in isolation, but when the choices are bracketed explicitly, then
4682 the choice seems to be driven by a naive diversification.

A.4 Experiment 4

4683 Experiment 4 investigated the effect of awareness on project choice. Experiment 1
4684 found an effect of awareness in the trial-by-trial data that was not replicated in
4685 Experiment 2. Above, this effect was explained through the law of small numbers:
4686 people may have been anticipating less risky gambles towards the end of the set. As
4687 such, the effect could be seen with more trials. Experiment 4 attempted to replicate
4688 the effect from Experiment 1 with 20 projects. The *naive* condition attempted to
4689 encourage participants to focus on projects one at a time and did not reveal the
4690 total number of projects. The *aware* condition attempted to encourage participants
4691 to think of all 20 projects. This was done by revealing the total number of projects
4692 in the beginning of the task and by identifying at each project display its order
4693 in the sequence. Experiment 4 again tested Hypothesis 2.4.

A.4.1 Method

A.4.1.1 Participants

4697 Two hundred and sixty-six people (110 female) were recruited from the online
4698 recruitment platform Prolific. Participants were compensated at a rate of £5 an
4699 hour. The average age was 40.62 ($SD = 9.59$, $min = 25$, $max = 74$). Participants
4700 reported an average of 7.45 ($SD = 7.8$, $min = 0$, $max = 47$) years of work in a

4701 business setting, and an average of 5.52 ($SD = 7.27$, $min = 0$, $max = 48$) years of
4702 business education. The mean completion time was 12.66 ($SD = 8.26$, $min = 1.48$,
4703 $max = 53.47$) minutes. Table A.3 shows the between-subjects condition allocation.

4704 A.4.1.2 Materials

4705 **A.4.1.2.1 Instructions** Participants were shown similar instructions to Ex-
periment 1 (see Section 2.2.1.2.1), except that the awareness manipulation was
incorporated into the text. Participants in the naive condition saw the instructions
in Figure A.23, and those in the aware condition saw the instructions in Figure A.24.

4709 **A.4.1.2.2 Risky investment task** Participants saw similar displays to those
in Experiment 3 (see Section A.3.1.2.2). However, here participants viewed 20
projects, so while the gamble constraints explained above were still applied, the
actual gamble values were different. Further, those in the aware condition saw
an added sentence that identified the number of the project they were currently

⁴⁷¹⁸ the number of projects they saw as 20.

A.4.1.3 Procedure

⁴⁷¹⁹ Participants read the instructions and completed the risky investment task in
⁴⁷²⁰ their respective conditions. After seeing the individual projects, participants were
⁴⁷²¹ then asked the four follow-up questions.
⁴⁷²²

A.4.2 Results

A.4.2.1 Project investment

⁴⁷²³ The project investment data were analysed as in Experiment 2 (see Section 2.3.2).
⁴⁷²⁴ Figures A.26 and A.27 show the choice and proportion data, respectively. The
⁴⁷²⁵ difference between awareness conditions was not significant, both in the logistic
⁴⁷²⁶ regression $b = -0.05$, 95% CI $[-0.22, 0.13]$, $z = -0.53$, $p = .595$, and in the t-test,
⁴⁷²⁷
⁴⁷²⁸ $d_s = -0.09$, 95% CI $[-0.33, 0.15]$, $t(264) = -0.73$, $p = .464$.
⁴⁷²⁹

A. Chapter 2 appendix

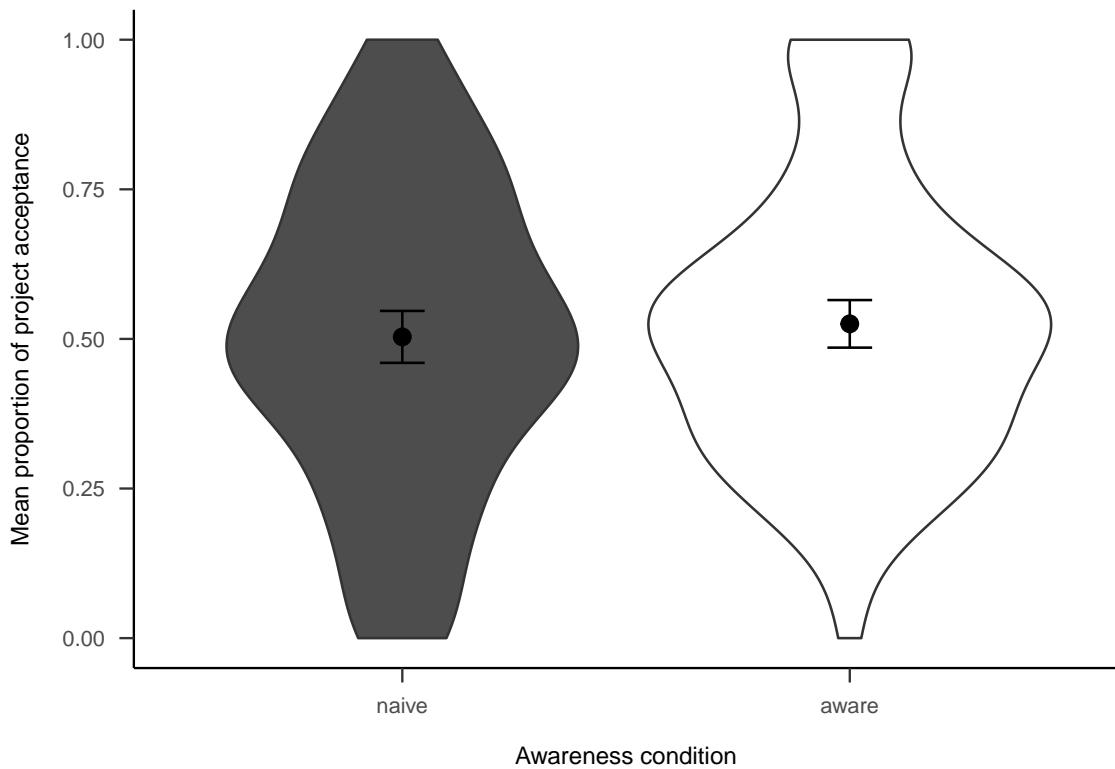

Figure A.27: Mean proportion of project acceptance for the awareness effect.

Table A.4: Logistic regression table of project acceptance by awareness and trial.

Term	$\hat{\beta}$	95% CI	z	p
Intercept	-0.01	[-0.20, 0.17]	-0.12	.907
Awareness1	-0.10	[-0.28, 0.09]	-1.05	.293
Project order	0.01	[0.00, 0.02]	1.66	.096
Awareness1 × Project order	0.00	[-0.01, 0.01]	0.29	.775

4730 Further, Figure A.28 shows the choice data as a function of the order of the project
 4731 in the sequence. As Table A.4 shows, there were no main effects or interactions.

4732 **A.4.2.2 Follow-up**

4733 **A.4.2.2.1 Project expectation** Participants were asked how many projects
 4734 they expected to see. Figure A.29 shows that those in the aware condition reportedly
 4735 expect to see more, $d_s = -0.94$, 95% CI [-1.19, -0.69], $t(264) = -7.67$, $p < .001$.
 4736 However, this is likely to be due to the fact that they were told how many

A. Chapter 2 appendix

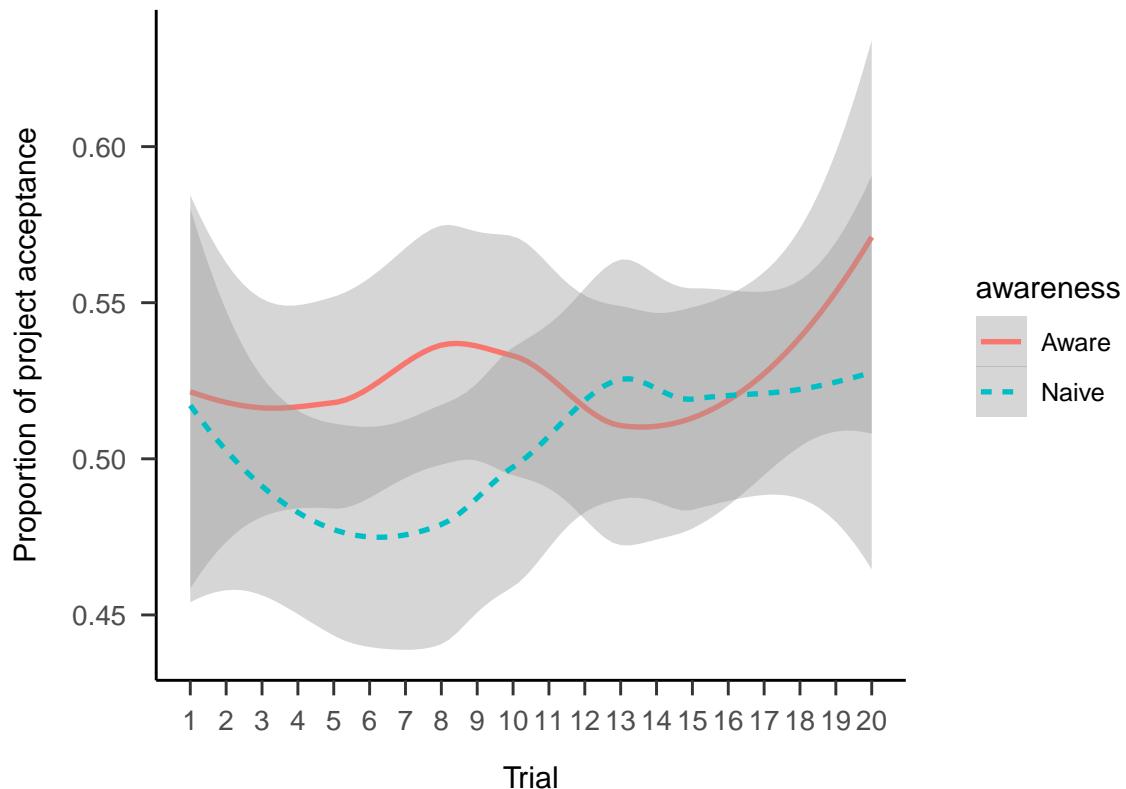

Figure A.28: Mean project acceptance by awareness and trial.

4737 projects there were.

4738 **A.4.2.2.2 Project number** Participants were asked how many projects they
 4739 thought they saw. Figure A.30 shows that overall people correctly estimated the
 4740 number of projects, with higher accuracy for those in the aware condition.

4741 **A.4.2.2.3 Portfolio choice - binary** Participants were then asked if they
 4742 would rather invest in all or none of the projects. As Figure A.31, there was no
 4743 significant difference between awareness conditions in wanting to invest in all of
 4744 the projects, $b = -0.09$, 95% CI $[-0.33, 0.15]$, $z = -0.74$, $p = .460$.

4745 **A.4.2.2.4 Portfolio choice - number** Subsequently, we asked participants
 4746 how many projects they would invest in out of the 20 that they saw. As Figure A.32
 4747 shows, the difference between awareness conditions was not significant, $d_s = -0.12$,
 4748 95% CI $[-0.36, 0.12]$, $t(264) = -0.97$, $p = .334$.

A. Chapter 2 appendix

Figure A.31: Mean choice of investing in all 20 projects for the awareness effect.

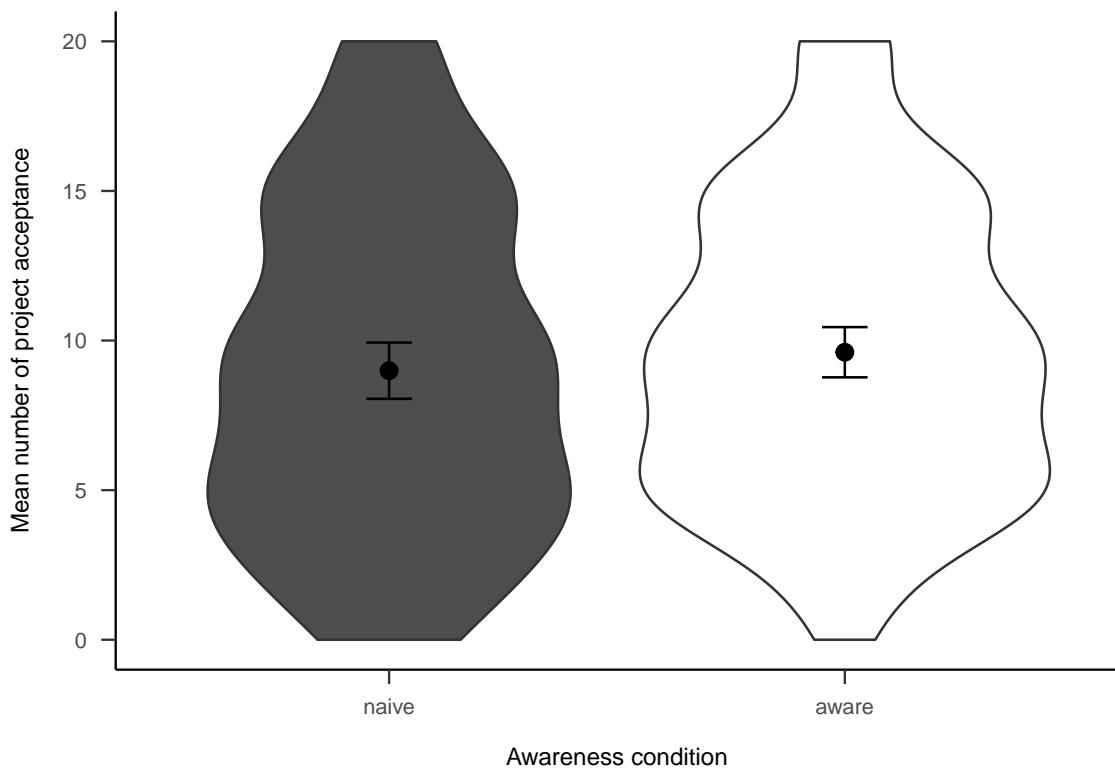

Figure A.32: Mean number of projects chosen in the follow-up for the awareness effect.

A. Chapter 2 appendix

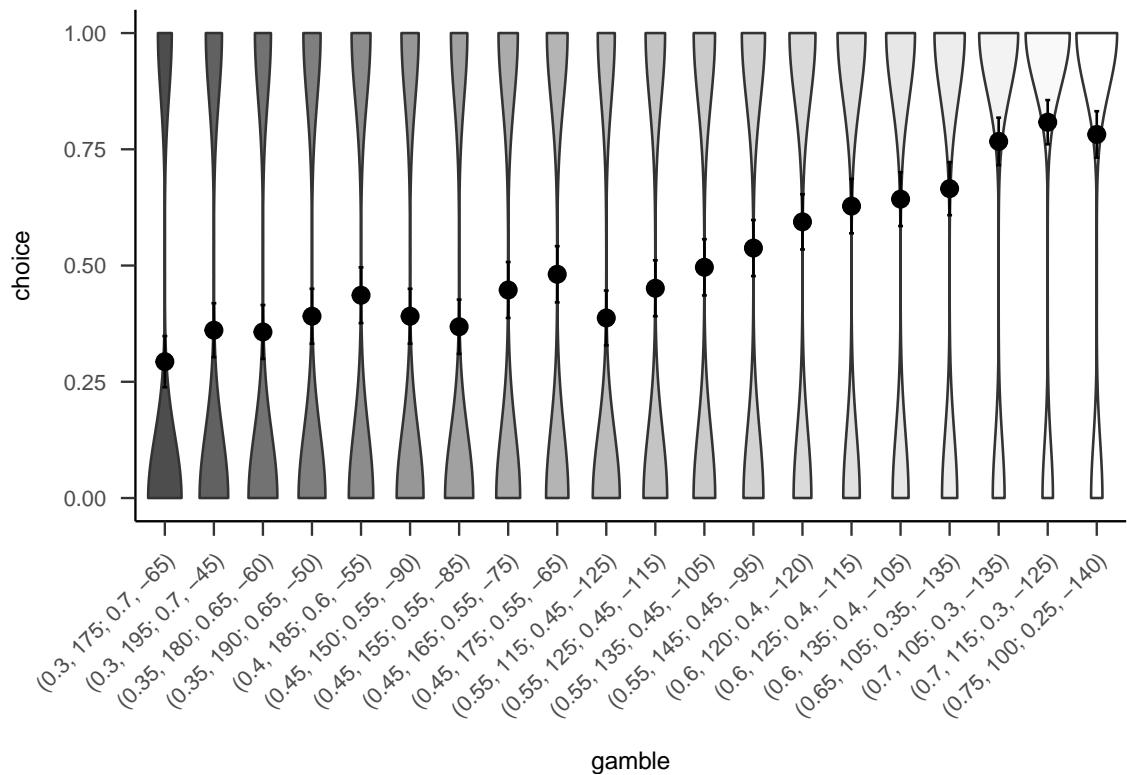

Figure A.33: Mean project acceptance for the 20 gambles. The format of the labels indicate: (gain probability, gain value; loss probability, loss value).

A.4.2.3 Gambles

Figures A.33 and A.34 show the overall people seemed to prefer gambles with higher probabilities of gain, sometimes regardless of expected value or value of the gain.

A.4.3 Discussion

Experiment 4 did not find evidence for Hypothesis 2.4. There was no significant effect of awareness on project choice by trial. Participants in the aware condition were expected to become less risk averse as they continued with the experiment if they were using a strategy similar to the law of small numbers. The fact that this effect was not replicated in Experiment 4 might mean that the finding in Experiment 1 was due to the specific gambles used in that experiment, or statistical chance.

A. Chapter 2 appendix

4794

4795

4796 This appendix contains supplementary materials and analyses for the three
4797 experiments reported in Chapter 4. In addition, five related experiments are
4798 reported. Experiment 4 was identical to Experiment 1, except that alignment was
4799 manipulated within-subjects, it did not include a no NPV condition, and there
4800 was no forecasting measure. Experiment 5 replicated Experiment 1, but only
4801 tested the forecasting effect and did so with a sample that had investing experience.
4802 Experiment 6 replicated Experiment 5 but with a larger sample size and a lay
4803 sample. Experiment 7 attempted to facilitate a use of numerical reliability through
4804 explicit hints. Experiment 8 tested both verbal and numerical reliability effects
4805 in an all within-subjects design. However, unlike Experiment 3, the design of
4806 Experiment 8 did not allow for a direct comparison of alignment conditions.

4808 B.1 Experiment 1

4809 In addition to the allocation measure, participants were also asked to rank the
4810 projects and forecast their future returns. The ranking task was included before
4811 the allocation task in order to encourage alignment and to have another measure of
4812 participants' decision-making. The forecasting task was added (described further
4813 below in Section B.1.1.1.2) in order to test whether the variance in people's forecasts
4814 is affected by alignment and NPV reliability.

4815 **Hypothesis B.1.** All allocation effects will replicate in the ranking measure.

4816 **Hypothesis B.2.** All allocation effects will replicate in the forecasting mean
4817 measure.

4818 In the forecasting measures, more alignable differences were expected to bring
4819 about more certainty about forecasting decisions, since participants will have more
4820 easily comparable information. As such, people's forecasting should be less variable

B. Chapter 4 appendix

4821 when comparing projects with alignable differences, than when comparing projects
4822 with non-alignable differences.

4823 **Hypothesis B.3.** The standard deviation of participants' forecasts will be higher,
4824 on average, in the low alignment condition than in the high alignment condition.

4825 B.1.1 Method

4826 B.1.1.1 Materials

4827 **B.1.1.1.1 Instructions** Figures B.1, B.2, and B.3 show the instructions given
4828 to those in the low NPV reliability, high NPV reliability, and no NPV condi-
4829 tion, respectively.

4830 **B.1.1.1.2 Forecasting** Participants were asked to respond to a forecasting task
4831 (adapted from Long et al., 2018), seen in Figure B.4. Participants were asked to
4832 predict each project's rate of return after one month. This allowed to calculate
4833 each participant's forecasting mean and standard deviation (the latter as inversely
4834 proportional to forecasting precision).

4835 **B.1.1.1.3 Ranking** As seen in Figure B.5, participants were asked to rank
4836 the projects in order of investment priority.

4837 **B.1.1.1.4 Confidence** As Figure B.6 shows, participants were asked to indicate
4838 how confident they were about each of their allocation decisions on a scale from
4839 0 ("Not confident at all") to 100 ("Extremely confident").

4840 **B.1.1.1.5 Justification** As Figure B.7 shows, participants were asked to justify
4841 their allocation decision in a free-response text-box.

B. Chapter 4 appendix

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided. In addition to those numbers, you will find each project's net present value (NPV), which is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. **The higher the NPV, the better the expectations for each project.** However, it is important to note that NPV is a very noisy measure relative to the other more specific measures because it relies on future forecasting. As such, **NPV is very unreliable and should be relied upon only as a last result; the specific project's measures should be used instead.**

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest objective value.** The features of the products that are listed matter because they reflect the direct value of the product, whereas financial measures such as NPV may reflect other factors, thus making it noisier, as mentioned above.

You will see a set of five different projects for which you must predict the investment returns after one month. For example, how likely is it that the project will return more than 9% after one month, how likely is it that the project will return 7% to 9%, etc.

You will also decide how to rank the projects in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Figure B.1: Experiment 1 low reliability instructions. Border added for clarity.

4842 B.1.2 Results

4843 B.1.2.1 Ranking

4844 A mixed factorial ANOVA was conducted to investigate the effects of alignment
4845 and verbally-instructed NPV reliability on participants' rankings of the target
4846 project. As seen in Figure B.8, the alignment \times reliability amount \times NPV amount
4847 interaction was significant, $F(6.62, 370.54) = 2.70, p = .011, \eta_p^2 = .046$. This
4848 effect seems to be driven by the differences between the no NPV condition and
4849 the conditions with NPV across the two alignment conditions. Specifically, in

B. Chapter 4 appendix

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided. In addition to those numbers, you will find each project's net present value (NPV), which is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. **The higher the NPV, the better the expectations for each project.** However, it is important to note that NPV is a very noisy measure relative to the other more specific measures because it relies on future forecasting. As such, NPV is very unreliable and should be relied upon only as a last result; the specific project's measures should be used instead. NPV is a very useful measure relative to the other more specific measures because it can be calculated regardless of the type of product. As such, **NPV is very reliable in most cases.**

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest objective value.**

You will see a set of five different projects for which you must predict the investment returns after one month. For example, how likely is it that the project will return more than 9% after one month, how likely is it that the project will return 7% to 9%, etc.

You will also decide how to rank the projects in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Figure B.2: Experiment 1 high reliability instructions. Border added for clarity.

4850 the low alignment condition, the linear NPV trend was significantly lower in the
4851 no NPV condition than both the low reliability condition, $M = -6.56$, 95% CI
4852 $[-10.26, -2.85]$, $t(112) = -3.50$, $p = .001$, and the high reliability condition,
4853 $M = -7.38$, 95% CI $[-10.83, -3.93]$, $t(112) = -4.24$, $p < .001$. However, in the
4854 high alignment condition, the linear NPV trend was only significantly lower in
4855 the no NPV condition than the high reliability condition, $M = -8.37$, 95% CI
4856 $[-11.85, -4.88]$, $t(112) = -4.76$, $p < .001$, and not the low reliability condition,
4857 $M = -1.71$, 95% CI $[-5.54, 2.13]$, $t(112) = -0.88$, $p = .380$.

B. Chapter 4 appendix

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided.

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest objective value**. The features of the products that are listed matter because they reflect the direct value of the product, whereas financial measures may reflect other factors.

You will see a set of five different projects for which you must decide how to rank in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Figure B.3: The instructions for the no NPV condition in Experiment 1. Border added for clarity.

Imagine that you have 100 points to assign to the following options for Project 1's rate of return on investment after one month. Assign points according to how likely you think each rate of return is.

	0	10	20	30	40	50	60	70	80	90	100
more than 9%											0
7% to 9%											0
5% to 7%											0
3% to 5%											0
1% to 3%											0
-1% to -3%											0
-5% to -7%											0
-7% to -9%											0
less than -9%											0
Total:											0

Figure B.8: Mean ranking.

B. Chapter 4 appendix

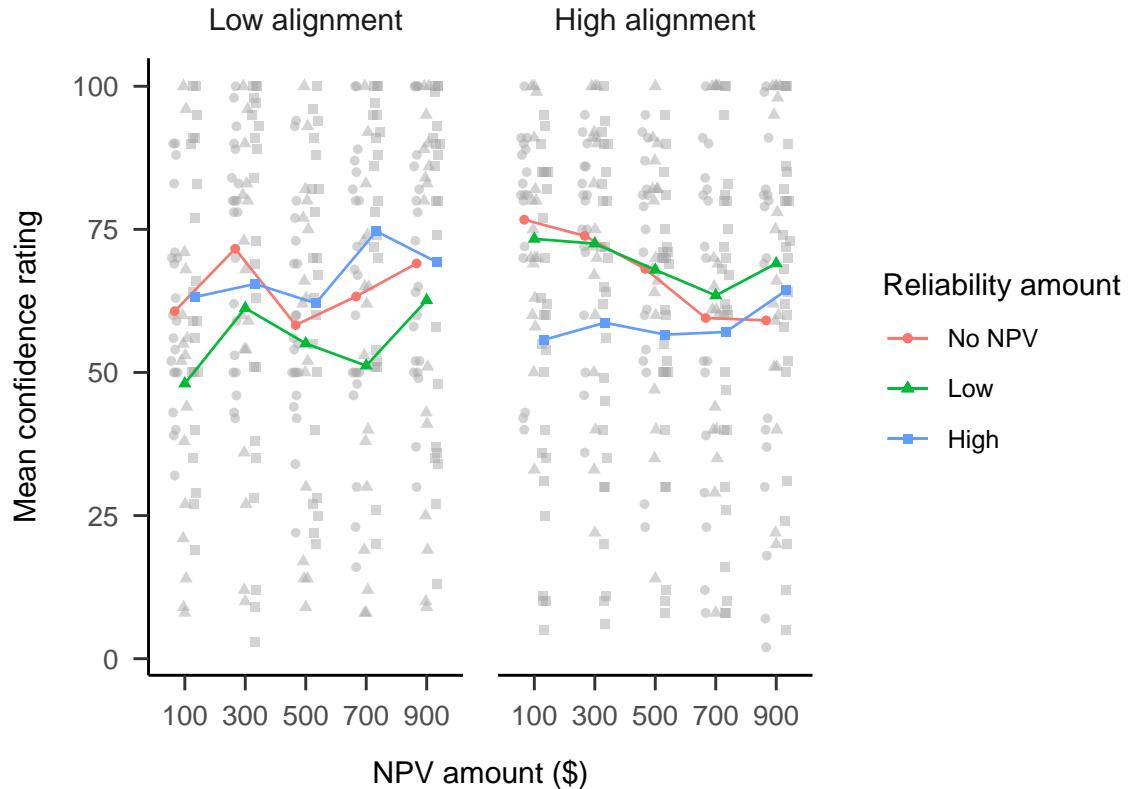

Figure B.9: Mean confidence.

B.1.2.2 Confidence

A mixed factorial ANOVA was conducted to investigate the effects of alignment and verbally-instructed NPV reliability on participants' confidence rating of their decisions. As seen in Figure B.9, the alignment \times reliability amount \times NPV amount interaction was not significant, $F(7.47, 418.08) = 1.26, p = .267, \eta_p^2 = .022$. Contrary to the allocation and ranking data, in the low alignment condition, there were no significant differences in the linear NPV trend between the no NPV condition and low reliability condition, $M = 10.73, 95\% \text{ CI } [-30.15, 51.61], t(112) = 0.52, p = .604$, nor the high reliability condition, $M = 13.05, 95\% \text{ CI } [-24.97, 51.07], t(112) = 0.68, p = .498$. However, as above, in the high alignment condition, the linear NPV trend was significantly lower in the no NPV condition than the high reliability condition, $M = 65.14, 95\% \text{ CI } [26.72, 103.57], t(112) = 3.36, p = .001$, and not the low reliability condition, $M = 31.88, 95\% \text{ CI } [-10.38, 74.14], t(112) = 1.49, p = .138$.

B. Chapter 4 appendix

B.1.2.3 Forecast mean

A mixed factorial ANOVA was conducted to investigate the effects of alignment and verbally-instructed NPV reliability on participants' forecast means. As seen in Figure B.10, the alignment \times reliability amount \times NPV amount interaction was not significant, $F(5.26, 142.10) = 1.89, p = .095, \hat{\eta}_p^2 = .066$. However, the alignment \times NPV amount interaction was significant, $F(2.63, 142.10) = 2.89, p = .044, \hat{\eta}_p^2 = .051$; as well as the reliability amount \times NPV amount interaction, $F(5.26, 142.10) = 7.91, p < .001, \hat{\eta}_p^2 = .227$. The simple effects appear to be as above. Specifically, in the low alignment condition, the linear NPV trend was significantly lower in the no NPV condition than both the low reliability condition, $M = 0.19, 95\% \text{ CI } [0.09, 0.30], t(54) = 3.63, p = .001$, and the high reliability condition, $M = 0.16, 95\% \text{ CI } [0.04, 0.28], t(54) = 2.75, p = .008$. However, in the high alignment condition, the linear NPV trend was only significantly lower in the no NPV condition than the high reliability condition, $M = 0.22, 95\% \text{ CI } [0.11, 0.32], t(54) = 4.04, p < .001$, and not the low reliability condition, $M = 0.08, 95\% \text{ CI } [-0.04, 0.21], t(54) = 1.30, p = .198$.

B.1.2.4 Forecast SD

A mixed factorial ANOVA was conducted to investigate the effects of alignment and verbally-instructed NPV reliability on participants' forecast SDs. As seen in Figure B.11, the alignment \times reliability amount \times NPV amount interaction was significant, $F(6.87, 185.42) = 2.91, p = .007, \hat{\eta}_p^2 = .097$. However, none of the linear NPV trends were significantly different from each other as above. Of relevance, the low alignment condition on average had higher SDs than those in the high alignment condition, $F(1, 54) = 5.77, p = .020, \hat{\eta}_p^2 = .097$.

B.1.3 Discussion

Hypothesis B.4 was not supported, as there was no evidence of a main effect of alignment on participants' confidence in their allocation decisions. Instead, exploratory analyses showed that the difference in confidence between reliability conditions is greater in the low alignment condition. This may reflect participants'

B. Chapter 4 appendix

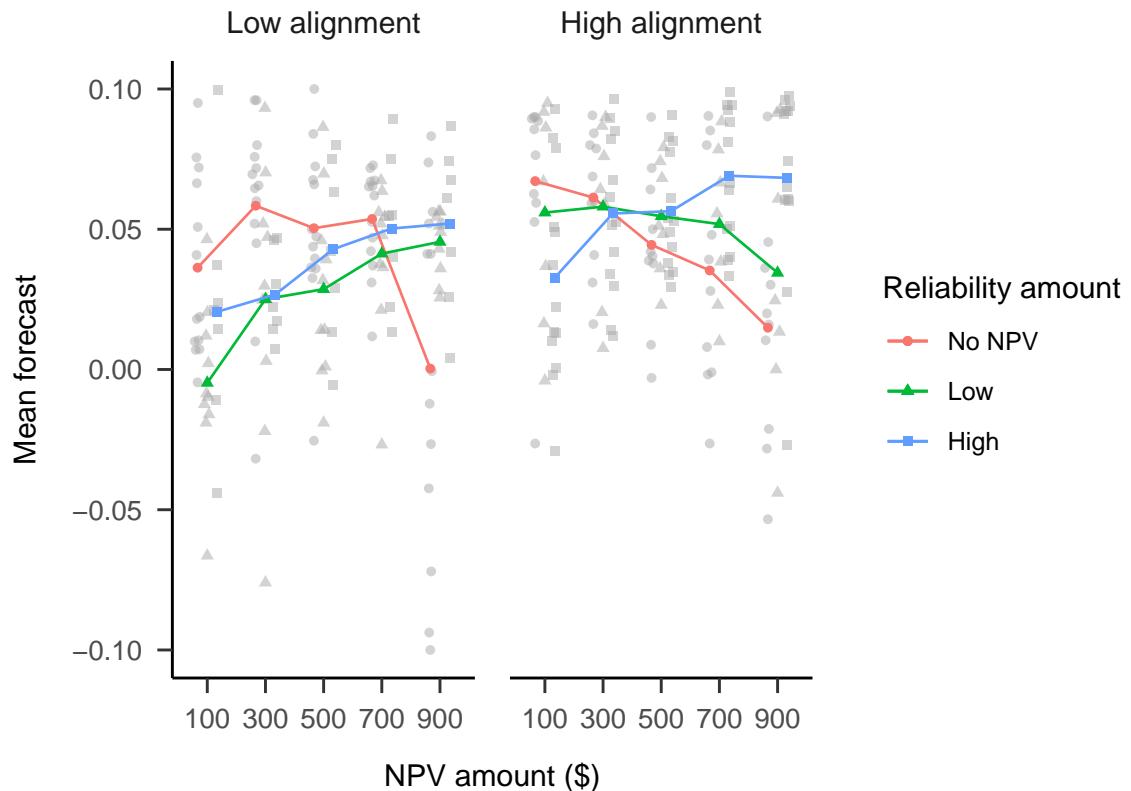

Figure B.10: Mean forecasts.

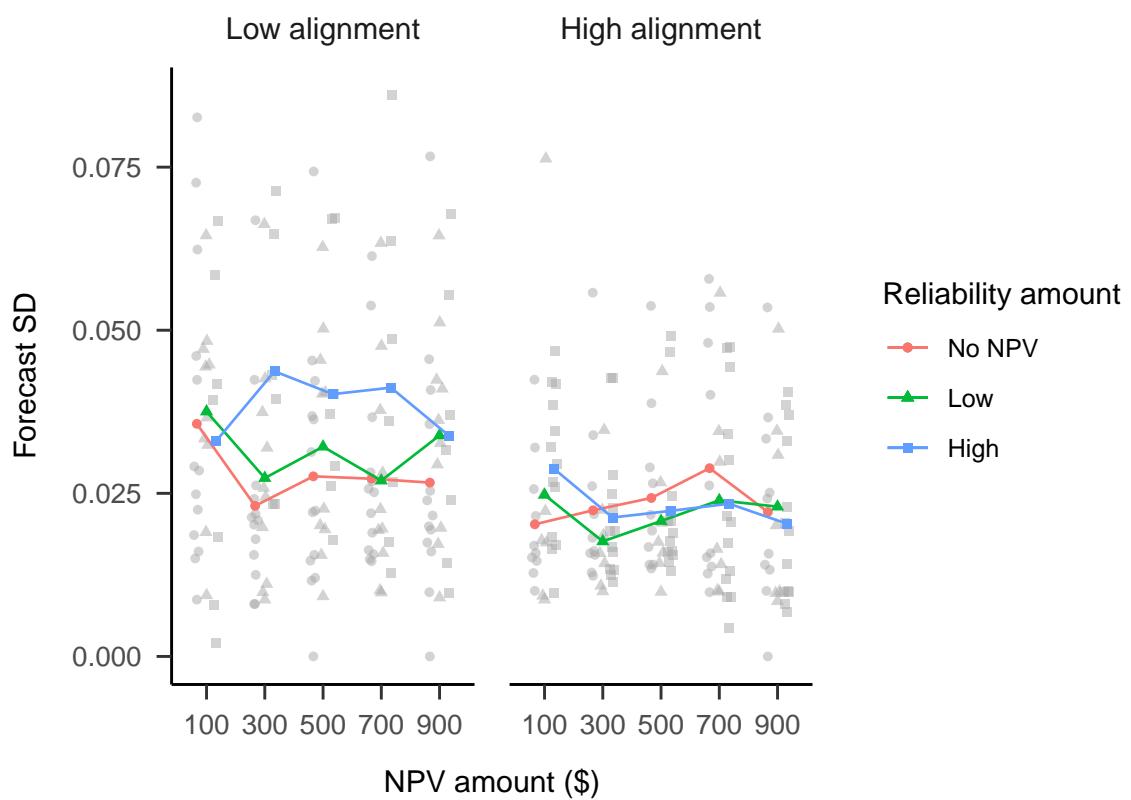

Figure B.11: Mean forecast SD.

B. Chapter 4 appendix

4899 difficulty in making sense of their choices when alignment was low, given more
4900 confidence when assured of the reliability of NPV. In the high alignment condition,
4901 on the other hand, regardless of reliability condition, they had a way of using
4902 the reliability information. Further, confidence also seemed to increase more with
4903 NPV, on average, more when projects were dissimilar, which provides evidence
4904 for their reliance on NPV in this situation. There was limited evidence for the
4905 effect of alignment on forecast variability. Experiments 5 and 6 attempted to
4906 replicate this result with more participants.

4907 B.2 Experiment 2

4908 B.2.1 Method

4909 B.2.1.1 Materials

4910 **B.2.1.1.1 Instructions** Figure B.12 shows the instructions.

4911 **B.2.1.1.2 NPV test** Participants were given more extensive information about
4912 NPV than in the previous experiment and were tested on their ability to calculate
4913 simple averages from given numerical ranges, as seen in Figures B.13 and B.14.

4914 **B.2.1.1.3 NPV knowledge ratings** A similar design to Long et al. (2018,
4915 Study 1) was used to test whether this sample may be overconfident in their
4916 understanding on NPV. Therefore, participants were asked to rate their knowledge
4917 of NPV in various points in the study (see the procedure in Section 4.3.1.3).

B. Chapter 4 appendix

Investment task

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided. In addition to those numbers, you will find each project's projected cash inflow for each year, and the net present value (NPV) that was calculated using those figures. The discount rate will always be 10% and the initial investment will always be \$5000. These are taken into account in the NPV calculations.

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest intrinsic quality.**

You will decide how to rank the projects in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Importantly, each page's set of five projects should be treated independently of the other pages' project sets.

Figure B.12: Experiment 2 instructions. Border added for clarity.

⁴⁹¹⁸ **B.2.1.1.4 Variance lecture** See below the slides for the variance lecture.

⁴⁹¹⁹ **B.2.2 Results**

⁴⁹²⁰ **B.2.2.1 Ranking**

⁴⁹²¹ A mixed factorial ANOVA was conducted to investigate the effects of NPV
⁴⁹²² amount, alignment, and numerical NPV reliability on participants' project rankings.
⁴⁹²³ Figure B.30 shows these data. The alignment \times reliability amount \times NPV amount
⁴⁹²⁴ interaction was not significant, $F(3.00, 159.10) = 2.44, p = .066, \hat{\eta}_p^2 = .044$. However,
⁴⁹²⁵ the alignment \times NPV amount interaction was significant, $F(3.31, 370.54) = 21.00,$
⁴⁹²⁶ $p < .001, \hat{\eta}_p^2 = .158$; as well as the reliability amount \times NPV amount interaction,
⁴⁹²⁷ $F(6.62, 370.54) = 9.73, p < .001, \hat{\eta}_p^2 = .148$. As in the allocation data, the linear

B. Chapter 4 appendix

Understanding NPV

Net Present Value (NPV) is used as a measure of a project's potential profitability. A positive value indicates that the project is profitable, while a negative value indicates that a project is not profitable.

When calculating NPV, the potential future cash inflows are converted to their "present values". This is important, because we know that an amount of money is more valuable in the present than it is in the future. The time value of money is accounted for by dividing each year's cash inflow by the discount rate. Finally, the sum of all the present values is deducted from the value of the initial investment.

To calculate the NPV you need the following components:

1. The cash inflow for each year of the project
2. The discount rate
4. The initial investment

Below is the generic formula for calculating NPV:

$$NPV = \frac{\text{Cash inflow for year 1}}{(1 + \text{discount rate})^1} + \frac{\text{Cash inflow for year 2}}{(1 + \text{discount rate})^2} + \frac{\text{Cash inflow for year 3}}{(1 + \text{discount rate})^3} \dots - \text{Initial investment}$$

Some of the time, it might be unclear exactly what the future cash inflow is, so it might be given as a range of possible values.

Below is an example of an NPV calculation with the discount rate calculations and initial investment already filled in. Notice that instead of a single cash inflow value, a range is provided (assume that the distribution is uniform). The value that should be used as the cash inflow is the mid point of these values. This is done by calculating the average of the two values.

For this session, you will get some practise in calculating NPV. However, we will give you the value that is in the denominator (the discount rate calculation) and the initial investment. All you need to do is calculate each year's cash inflow and enter them into the formula.

Example 1

$$NPV = \frac{[\text{range: } 1500 - 2500]}{1.1} + \frac{[\text{range: } 750 - 1250]}{1.21} + \frac{[\text{range: } 1875 - 3125]}{1.331} - 3000$$

Please calculate the mid-points for these ranges and type them in below:

Year 1 cash inflow	<input type="text"/>
Year 2 cash inflow	<input type="text"/>
Year 3 cash inflow	<input type="text"/>

Figure B.13: Experiment 2 NPV test. Border added for clarity.

B. Chapter 4 appendix

The range for Year 1 was \$1500-\$2500.
You calculated the Year 1 cash inflow to be \$2000.

The range for Year 2 was \$750-\$1250.
You calculated the Year 2 cash inflow to be \$1000.

The range for Year 3 was \$1875-\$3125.
You calculated the Year 3 cash inflow to be \$2500.

Therefore, NPV = \$1522.92

Figure B.14: Experiment 2 NPV test answers. Border added for clarity.

Please rate your knowledge of Net Present Value (NPV) on this 1-7 scale:

Shallow			Partial			Deep
1	2	3	4	5	6	7

NPV knowledge

Figure B.15: Experiment 2 NPV knowledge rating task. Border added for clarity.

NPV variance

Figure B.16: Variance lecture slide 1.

B. Chapter 4 appendix

NPV

$$NPV = \frac{Year 1 \text{ inflow}}{(1+discount \%)^1} + \frac{Year 2 \text{ inflow}}{(1+discount \%)^2} + \frac{Year 3 \text{ inflow}}{(1+discount \%)^3} \dots - Initial \text{ investment}$$

Figure B.17: Variance lecture slide 2.

NPV is used very frequently

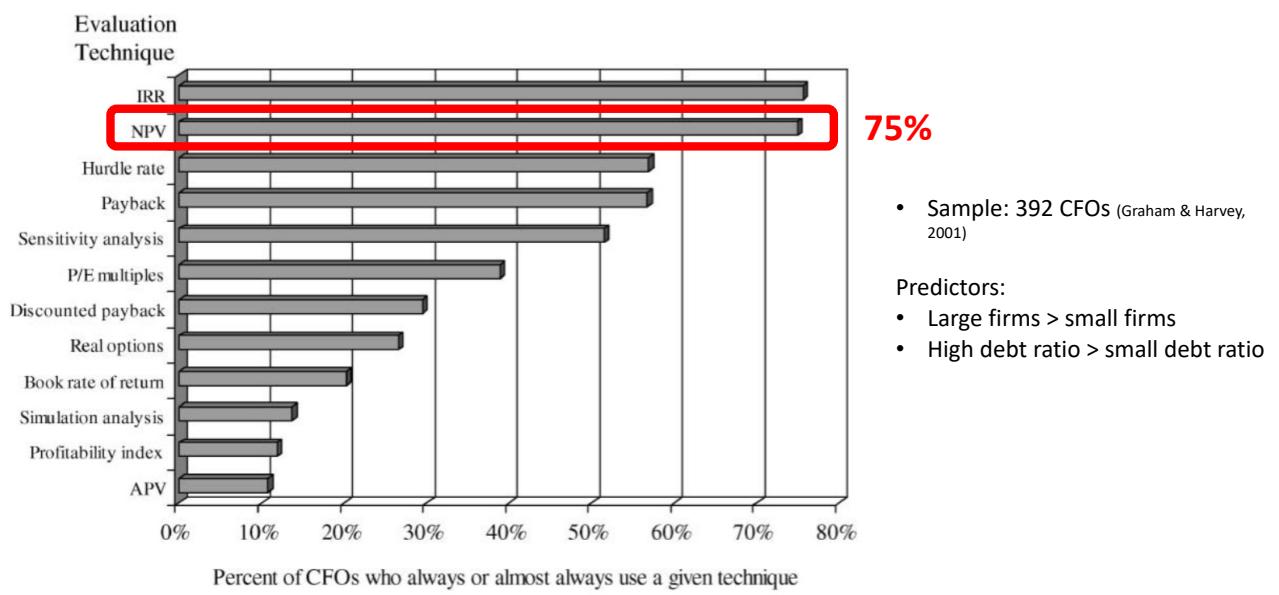

Figure B.18: Variance lecture slide 3.

The NPV paradox

- “Although the NPV method is criticized by both practitioners and academics, the traditional NPV calculation is by far the most commonly used tool for [exploration & production] project valuation.” (Willigers et al., 2017)
- “NPV is almost always applicable but is almost always wrong” (Fox, 2008)
- “the NPV rule as governing all capital budgeting decisions may not be appropriate” (Arya et al., 1998)

Figure B.19: Variance lecture slide 4.

Consequences

- Researchers studied 174 cases of fraudulent financial reporting
 - Fraudulent “facts” vs “forecasts”
- Forecasts based on unreasonable accounting assumptions
 - Form 40% of fraud cases
 - Account for 44% of economic losses
- Total damages by fraudulent *facts*: US\$ 27 billion
- Total damages by fraudulent *forecasts*: US\$ 23 billion

Figure B.20: Variance lecture slide 5.

B. Chapter 4 appendix

NPV

$$NPV = \frac{\text{Year 1 inflow}}{(1+discount\%)^1} + \frac{\text{Year 2 inflow}}{(1+discount\%)^2} + \frac{\text{Year 3 inflow}}{(1+discount\%)^3} \dots - \text{Initial investment}$$

Where do these cash inflows come from?

Figure B.21: Variance lecture slide 6.

“It’s impossible to forecast most projects’ actual cash flows accurately” (Myers, 1984)

Figure B.22: Variance lecture slide 7.

Forecasting is error-prone

- Future forecasts tend to be overly-optimistic
 - For longevity
 - For relationships
 - When dopamine is increased
 - In animal behaviour
- Executives are similarly overly-optimistic
 - In stock market returns
 - For firm earnings

Figure B.23: Variance lecture slide 8.

Forecasting is error-prone

- CFO survey between 2001-2011
- *Over the next year, I expect the annual S&P 500 return will be:*
 - *There is a 1-in-10 chance the actual return will be less than ____%.*
 - *I expect the return to be: ____%.*
 - *There is a 1-in-10 chance the actual return will be greater than ____%.*
- 13,346 estimates

Figure B.24: Variance lecture slide 9.

Forecasting is error-prone

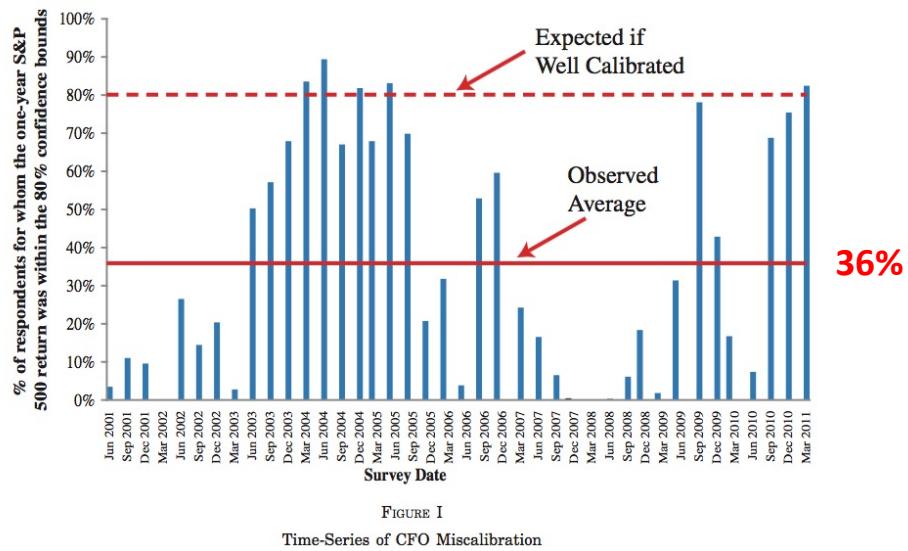

Figure B.25: Variance lecture slide 10.

Paying attention to variance

- Ranges are frequently used for forecast estimates
 - 80% of the time between 2002-2010
- Taking account of variance increases forecasting accuracy

Figure B.26: Variance lecture slide 11.

Paying attention to variance - Example

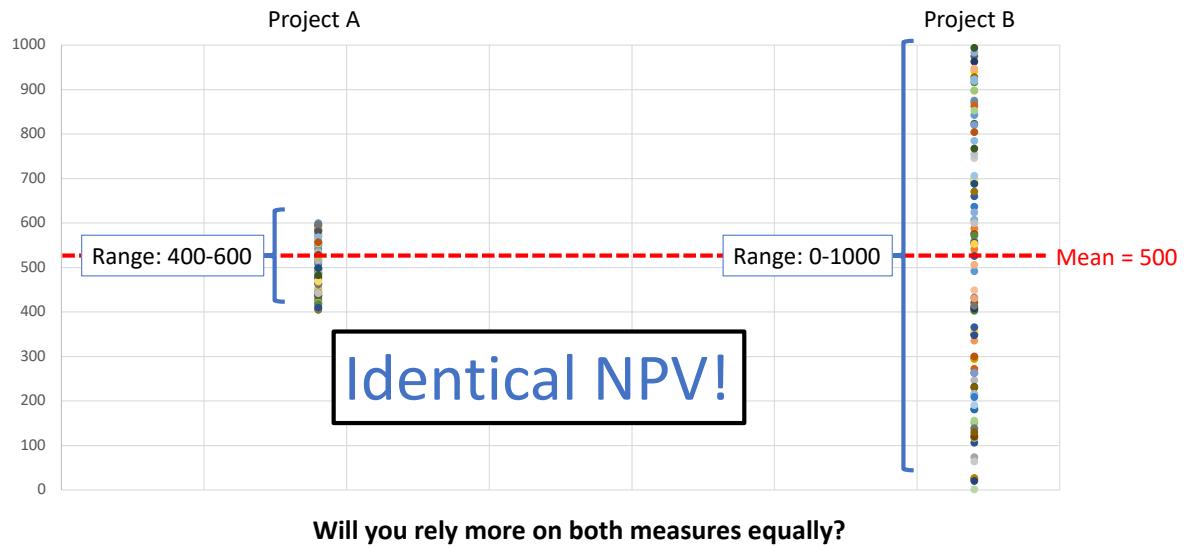

Figure B.27: Variance lecture slide 12.

Summary

- NPV is used a lot, but criticised by some
- The costs of poor forecasting are potentially high
- NPV relies on forecasting
- Executives may underestimate forecast variance

Figure B.28: Variance lecture slide 13.

Bottom line

- Pay attention to cash inflow variance
- Not all NPVs are created equal
 - NPV based on more variance should be weighted less than other measures

Figure B.29: Variance lecture slide 14.

4928 NPV trend did not differ between reliability amount condition in neither the low
4929 alignment condition, $\Delta M = 0.43$, 95% CI $[-0.77, 1.63]$, $t(53) = 0.71$, $p = .480$,
4930 nor the high alignment condition, $\Delta M = 0.46$, 95% CI $[-0.92, 1.84]$, $t(53) = 0.67$,
4931 $p = .504$. However, averaging over reliability amount, the linear NPV trend
4932 was higher in the low alignment condition than in the high alignment condition,
4933 $\Delta M = -4.54$, 95% CI $[-6.39, -2.68]$, $t(53) = -4.91$, $p < .001$.

4934 **B.2.2.2 Confidence**

4935 A mixed factorial ANOVA was conducted to investigate the effects of NPV
4936 amount, alignment, and numerical NPV reliability on participants' confidence
4937 ratings. Figure B.31 shows these data. Only the main effect of NPV amount was
4938 significant, $F(2.62, 139.08) = 2.97$, $p = .041$, $\eta_p^2 = .053$.

B. Chapter 4 appendix

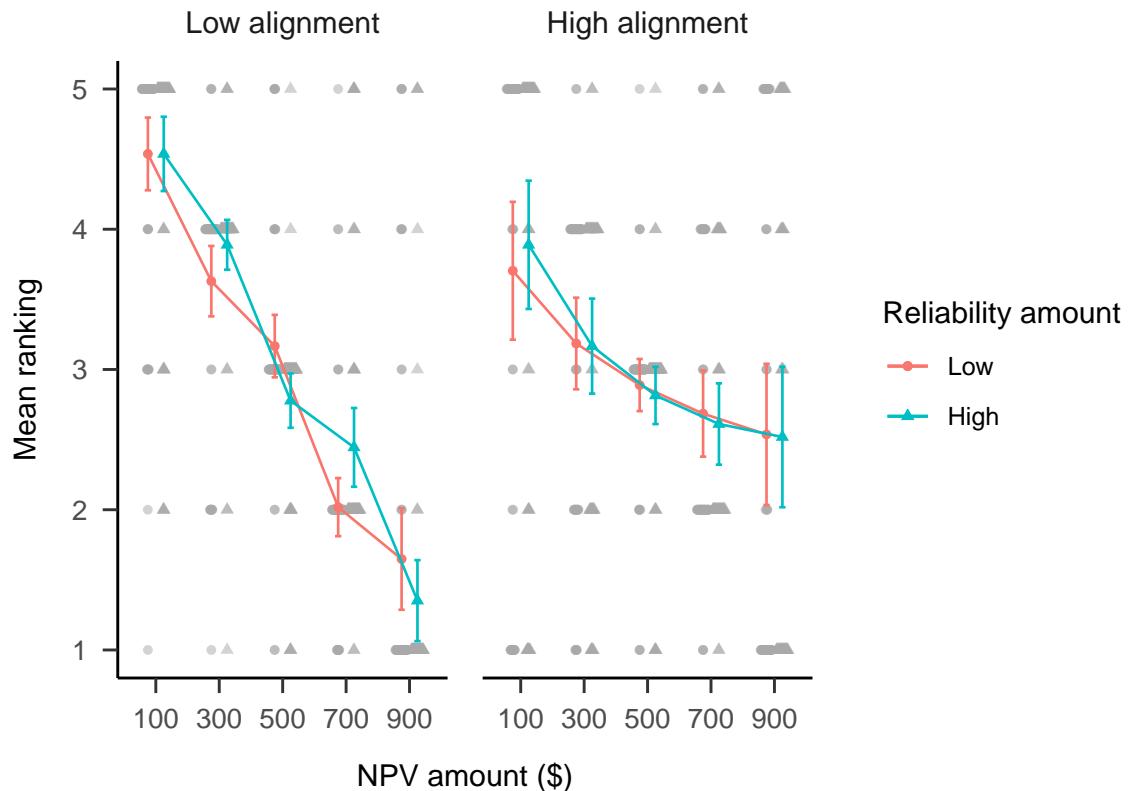

Figure B.30: Mean ranking.

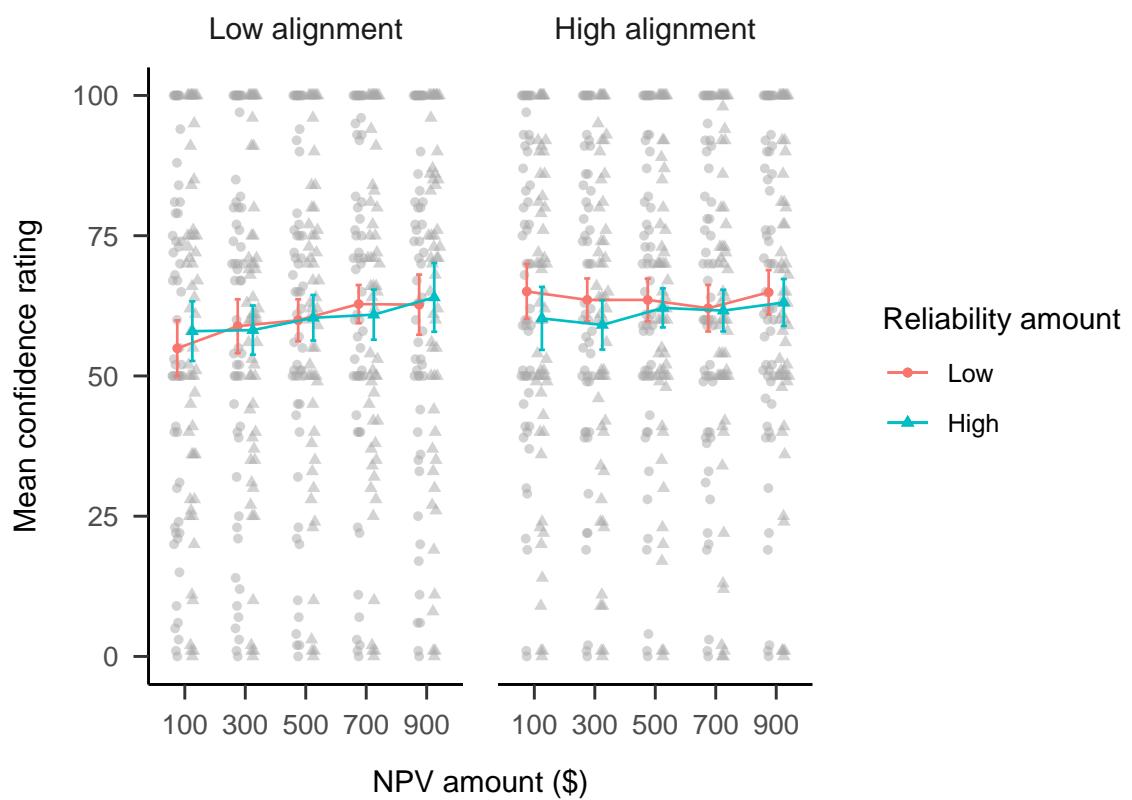

Figure B.31: Mean confidence.

B. Chapter 4 appendix

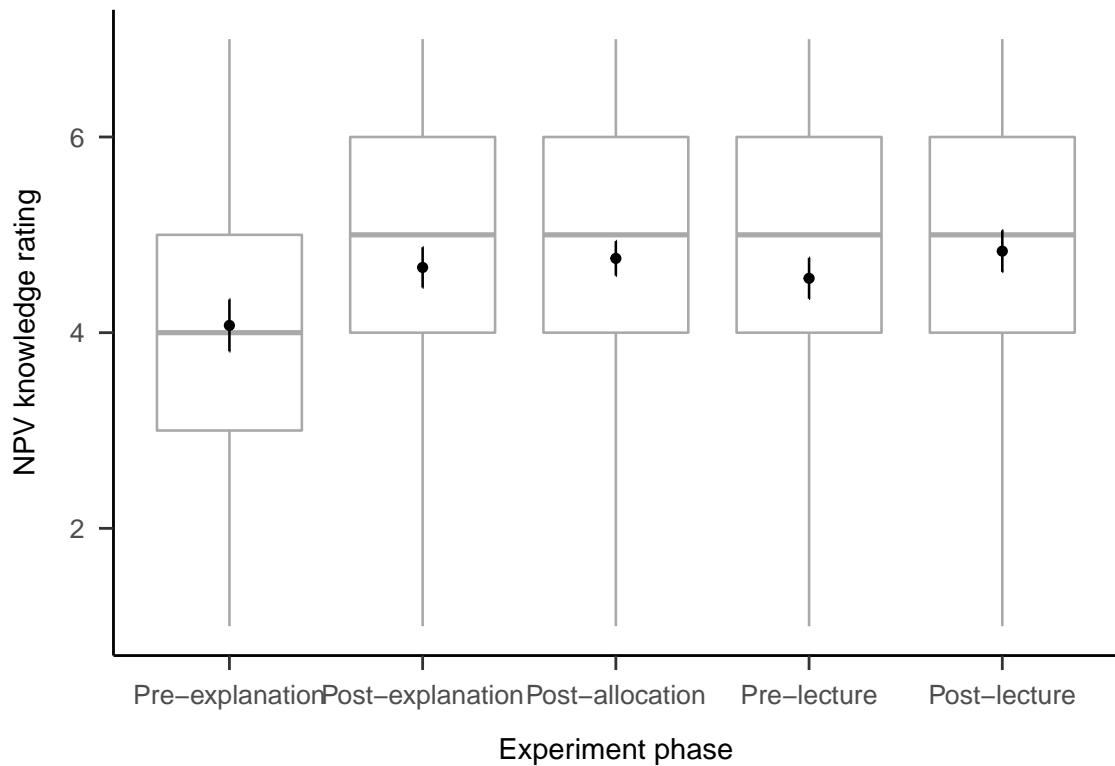

Figure B.32: Mean NPV knowledge rating.

4939 **B.2.2.3 NPV knowledge**

4940 A repeated-measures ANOVA was conducted to investigate the effects of
4941 experiment phase condition on participants' NPV knowledge rating. Figure B.32
4942 shows these data. The main effect of phase was significant, $F(2.43, 128.59) = 7.80$,
4943 $p < .001$, $\hat{\eta}_p^2 = .128$. The post-explanation rating was significantly higher than
4944 the pre-explanation rating, $\Delta M = -0.59$, 95% CI $[-0.92, -0.26]$, $t(53) = -5.07$,
4945 $p < .001$. However, there were no significant differences in rating between any
4946 of the later phases.

4947 **B.3 Experiment 3**

4948 Figure B.33 shows the simulated hypothesised effects for Experiment 3. These
4949 effects were constructed as a composite of Experiment 1 data (without the no
4950 NPV condition) for the verbal reliability type condition, and data from a pilot
4951 study (see Appendix B.8) for the numerical reliability type condition. Variance
4952 was removed to see the effects clearer.

B. Chapter 4 appendix

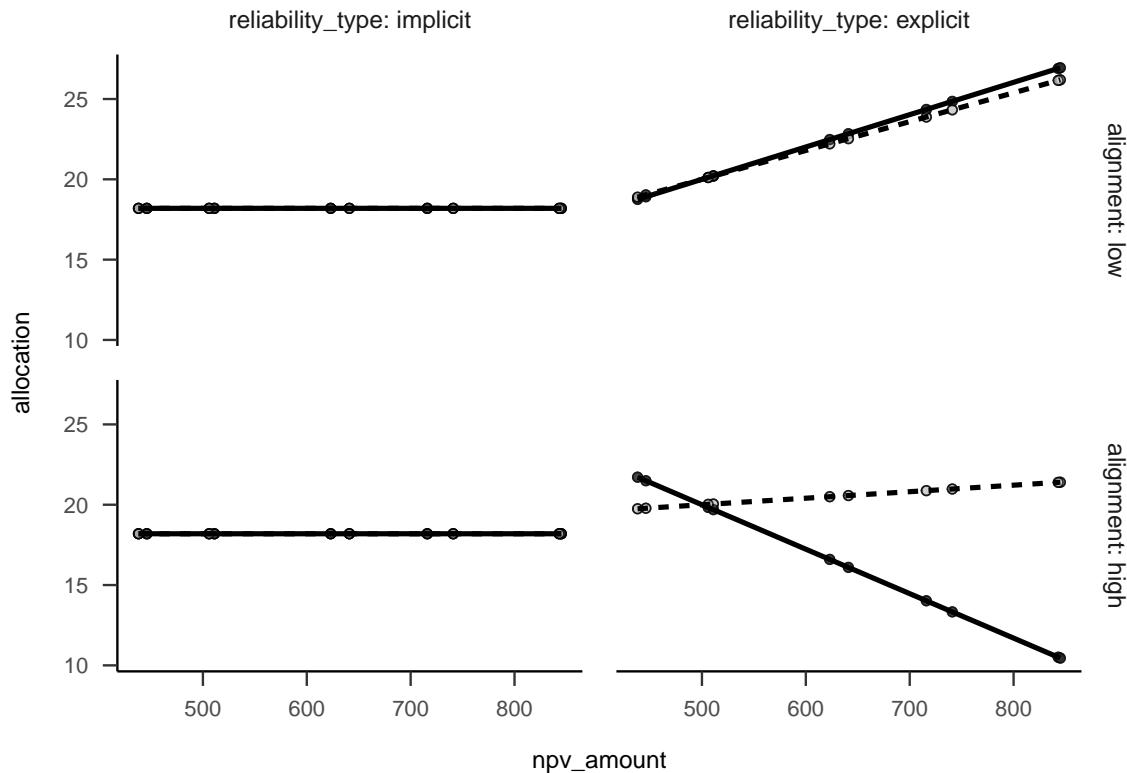

Figure B.33: Experiment 3 predicted data.

4953 **B.3.1 Method**

4954 **B.3.1.1 Participants**

4955 **B.3.1.1.1 Power analysis** A power analysis was conducted through simulation
4956 of the effects hypothesised in Experiment 3 (and the simple effects implied by them).
4957 The simulated data used the same regression coefficients as Experiment 2 for the
4958 explicit condition, no effects for the implicit condition (as shown in Figure B.33),
4959 and the intercept and residual variance of Experiment 2. The null effects were
4960 analysed using the two one-sided tests (TOST) procedure, or *equivalence* testing
4961 (Lakens et al., 2018), and setting the smallest effect size of interest to the smallest
4962 difference that leads to a significant equivalence between low and high implicit
4963 reliability for low alignment in Experiment 8 (see Appendix B.8). Figure B.34 shows
4964 the resulting power curve. The analysis suggests a total sample size of 448 ($112 \cdot 4$).

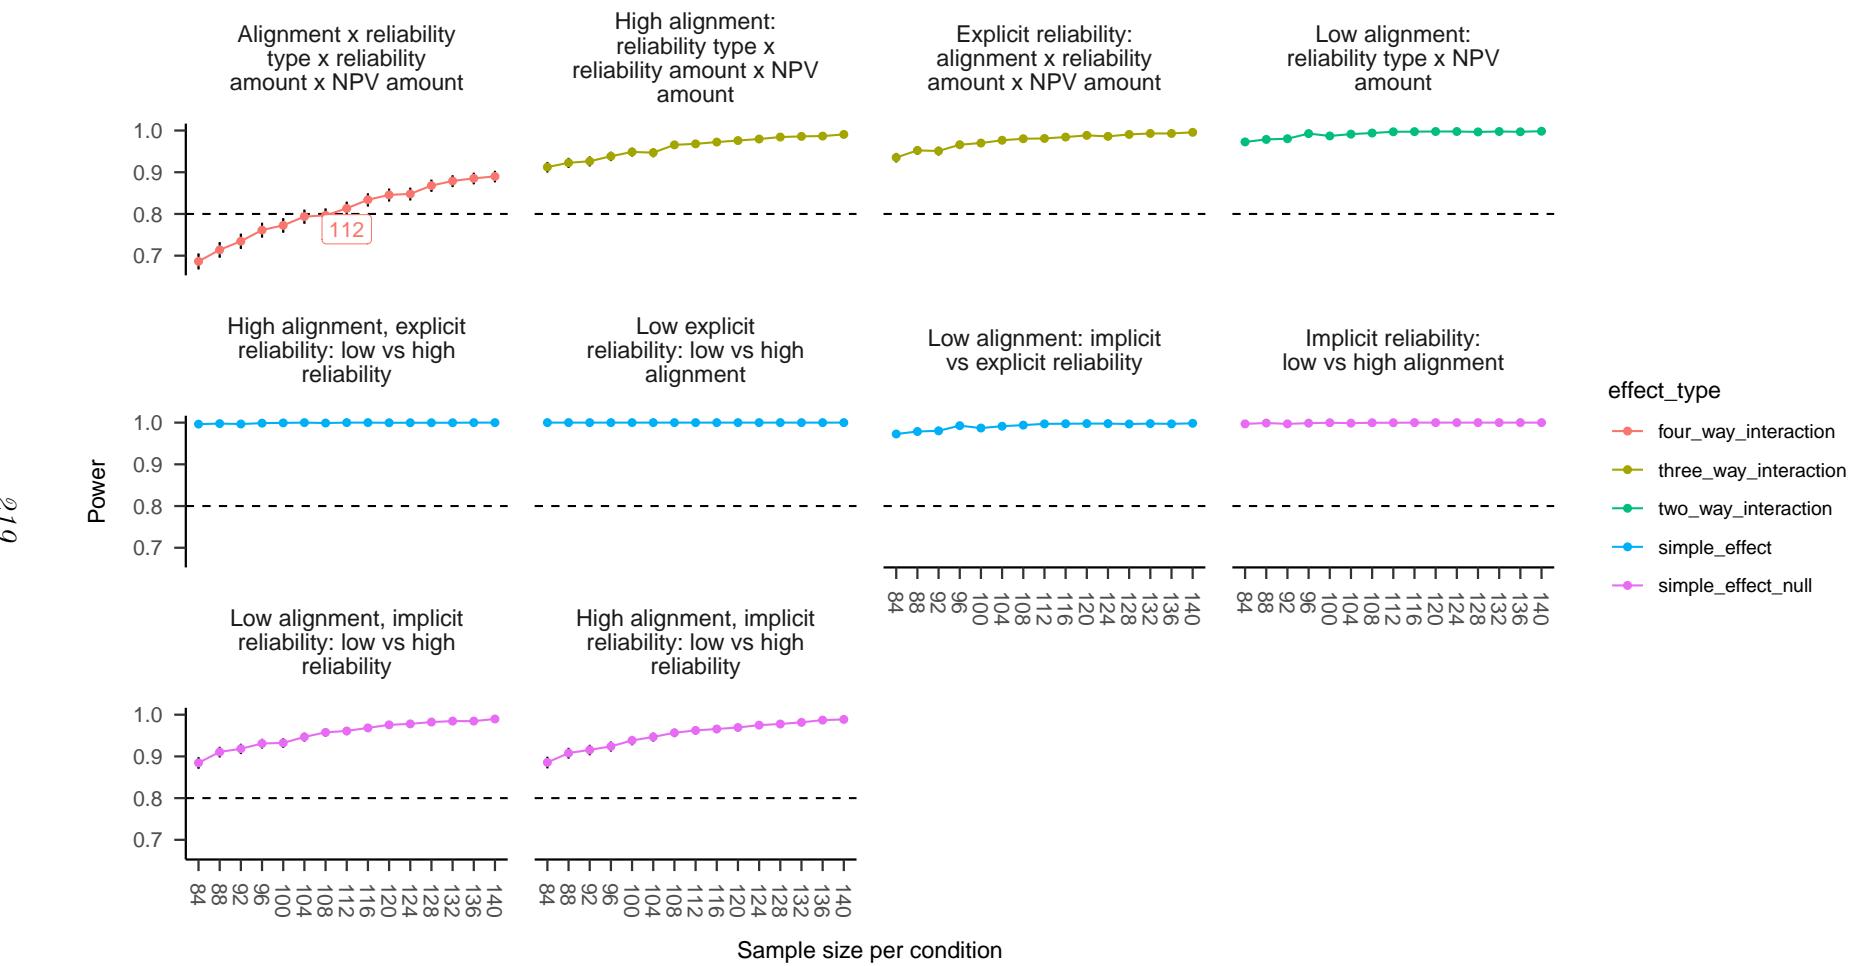

Figure B.34: Alignment Experiment 3 power curve. Labels indicate lowest sample size above 80% power.

B. Chapter 4 appendix

B.3.1.2 Materials

B.3.1.2.1 Instructions Figures B.35 and B.36 show the instructions for the verbal and numerical reliability conditions, respectively.

B.3.1.2.2 Interstitial display Figure B.37 shows an example of an interstitial display.

B.3.2 Results

B.3.2.1 Allocation

The three-way interaction (reliability amount \times NPV amount \times reliability type) in the high alignment condition was significant, $\Delta M = 35.43$, 95% CI [20.74, 50.12], $t(444) = 4.74$, $p < .001$. The NPV amount \times reliability type (averaging over reliability amount) in the low alignment condition was significant, $\Delta M = 11.48$, 95% CI [0.19, 22.77], $t(444) = 2.00$, $p = .046$. The association between allocation and NPV amount for those in the explicit low reliability condition was significantly stronger for those in the low alignment condition, than for those in the high alignment condition, $\Delta M = 35.68$, 95% CI [22.27, 49.09], $t(444) = 5.23$, $p < .001$. The linear NPV amount trend for those in the low alignment condition was significantly stronger for those in the explicit reliability condition, than for those in the implicit reliability condition (averaging over reliability amount), $\Delta M = 11.48$, 95% CI [0.19, 22.77], $t(444) = 2.00$, $p = .046$. The linear NPV amount trend for those in the implicit reliability condition was not significantly “equivalent” between those in the low and high reliability conditions for both those in the low alignment $\Delta M = 1.64$, 95% CI [-8.74, 12.03], $t(444) = 0.31$, $p = .620$ and high alignment conditions $\Delta M = -1.21$, 95% CI [-11.59, 9.18], $t(444) = 0.22$, $p = .589$. However, this is likely to be because the “lowest effect size of interest” estimate originated from an analysis used before data collection that was different to the one that one used after data collection. Specifically, a univariate linear model was originally used (treating NPV amount as a continuous predictor), whereas the data were ultimately analysed using a multivariate linear model (treating NPV amount as a repeated measures factor).

B. Chapter 4 appendix

Imagine that you are a CEO of a large company composed of many individual businesses.

You will be shown information about a number of projects that your company is considering to invest in. Each project is independent of the others. Some specific information about the project itself is provided. In addition to those numbers, you will find each project's net present value (NPV), which is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. The higher the NPV, the better the expectations for each project.

For each project, you will see an NPV, alongside a statement of whether NPV is considered to be a reliable (or an unreliable) metric for that project. There are usually a range of plausible NPV outcomes, so when NPV is considered to be "reliable" this means that the range of possible values is relatively narrow (indicating high confidence in the estimate). Conversely, when NPV is considered to be "unreliable", this means that the range of possible values is relatively wider (indicating low confidence in the estimate).

Your task is to rank the projects in order of investment priority and decide how to allocate the available budget (as a percentage) between them.

Test yourself on the above instructions. If Project A has an NPV of \$100, and Project B has an NPV of \$200, write in the following text box the name of the project that has a greater expectation of profit: Project

Continue

Figure B.35: Experiment 3 verbal reliability instructions. Border added for clarity.

B.4 Experiment 4

4993 Experiment 4 further investigated the effects of alignment and verbal NPV
4994 reliability information on capital allocation decisions. Experiment 4 used the same
4995 methodology as in Experiment 1 (see Section 4.3.1), except for two main changes.
4996 First, the alignment conditions were manipulated within subjects. Second, the no
4997 NPV condition in the NPV reliability variable was removed.

4998 The results of Experiment 1 were expected to replicate (see Section 4.3.2).
4999 Specifically, it was expected that in the high alignment condition, participants
5000 will be able to respond to each reliability condition, whereas, in the low alignment
5001 condition, they will rely more on NPV regardless of reliability condition.

5002 In addition to the all-project allocation data analysed above, analyses for just the

You will be shown information about a number of projects that your company is considering to invest in. Each project is independent of the others. Some specific information about the project itself is provided. In addition to those numbers, you will find each project's net present value (NPV), which is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. The higher the NPV, the better the expectations for each project.

For each project, you will see a range of possible NPVs alongside a 'midpoint'. The range literally represents the range of plausible outcomes (a uniform distribution), but the midpoint is the best guess, and hence is the same as a single NPV. That is, all values within the range are equally likely, but the midpoint is still the best guess because it is the value that is closest to all the other values.

Your task is to rank the projects in order of investment priority and decide how to allocate the available budget (as a percentage) between them.

Test yourself on the above instructions. If Project A has an NPV of \$100, and Project B has an NPV of \$200, write in the following text box the name of the project that has a greater expectation of profit: Project

“target project” are also reported. This refers to allocation of capital to the project that had the highest NPV, but the lowest value on concrete measures intrinsic to the actual product (e.g., the capacity of a laptop in gigabytes). Therefore, a higher allocation value indicated a higher reliance on NPV. Further, the method and analyses for the confidence measure are also reported.

Hypothesis B.4. Participants will be more confident about their decisions in the high alignment condition than in the low alignment condition.

B.4.1 Method

B.4.1.1 Participants

Seventy-one people (44 female) were recruited from the online recruitment platform Prolific. Participants were compensated at a rate of £5 an hour. The average age was 33.27 ($SD = 10.21$, $min = 18$, $max = 65$). Table B.1 shows the between-subjects condition allocation. The two alignment conditions (low and high) were presented within subjects and the order of their presentation was randomised. Further, NPV amount was varied within subjects.

B.4.1.2 Materials

The project display, allocation task, and confidence task were the same as in Experiment 1 (see Section 4.2.1.2).

B.4.1.2.1 Instructions Participants were shown similar instructions to Experiment 1 (see Section 4.2.1.2.1), except for the addition of references to the multiple

B. Chapter 4 appendix

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided. In addition to those numbers, you will find each project's net present value (NPV), which is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. **The higher the NPV, the better the expectations for each project.** However, it is important to note that NPV is a very noisy measure relative to the other more specific measures because it relies on future forecasting. As such, **NPV is very unreliable and should be relied upon only as a last result; the specific project's measures should be used instead.**

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest objective value.** The features of the products that are listed matter because they reflect the direct value of the product, whereas financial measures such as NPV may reflect other factors, thus making it noisier, as mentioned above.

You will see a set of five different projects in each page, and for each set you must decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects. Critically, treat each set of projects as independent of one another; one page's project set allocation does not impact another page's allocation.

Figure B.39: Experiment 4 high reliability instructions. Border added for clarity.

seen in Figure B.40, the alignment \times reliability amount \times NPV amount interaction was not significant, $F(3.64, 250.93) = 1.71, p = .153, \hat{\eta}_p^2 = .024$. This is most likely due to the fact that the reliability amount \times NPV amount interaction was significant in the high alignment condition, $\Delta M = -64.82, 95\% \text{ CI } [-102.70, -26.93], t(69) = -3.41, p = .001$, the low alignment condition, $\Delta M = -37.74, 95\% \text{ CI } [-70.92, -4.56], t(69) = -2.27, p = .026$, as well as averaging over alignment conditions, $F(2.98, 205.65) = 4.90, p = .003, \hat{\eta}_p^2 = .066$. Despite this, the alignment \times NPV amount interaction was significant, $F(3.64, 250.93) = 3.19, p = .017, \hat{\eta}_p^2 = .044$, such that the linear trend of NPV amount was stronger in the low alignment, $\Delta M = 13.28, 95\% \text{ CI } [-3.31, 29.87], t(69) = 1.60, p = .115$ than in the high alignment condition, $\Delta M = -10.67, 95\% \text{ CI } [-29.62, 8.27], t(69) = -1.12, p = .265$. However, neither of these trends were individually significant.

B. Chapter 4 appendix

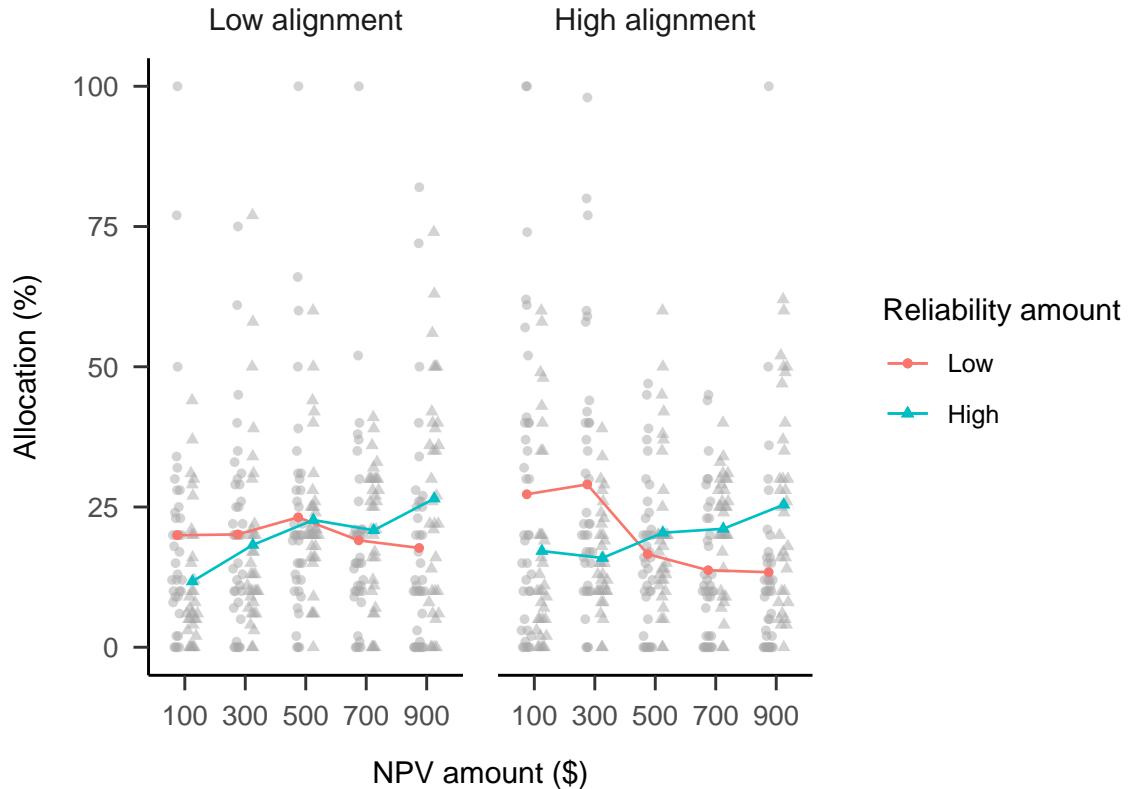

Figure B.40: Mean project allocation in Experiment 4. Error bars represent 95% confidence intervals based on the multivariate model. Note that this mixed factorial design does not allow for using confidence intervals to make inferences by “eye” across conditions.

5044 B.4.2.1 Confidence

5045 A mixed factorial ANOVA was conducted to investigate the effects of alignment,
 5046 verbal NPV reliability, and NPV amount on participants’ confidence in their
 5047 allocations. As seen in Figure B.41, the difference between alignment conditions
 5048 was not significant, $F(1, 69) = 2.76, p = .101, \eta_p^2 = .038$. However, the reliability
 5049 \times alignment interaction was significant, as well as the NPV amount \times alignment
 5050 interaction. An exploratory analysis was conducted of the relevant simple effects
 5051 for each interaction, applying a Šidák correction to the p values for each effect.
 5052 None of the simple effects were significant after the correction.

5053 The raw mean differences indicated that there was a greater difference between
 5054 reliability conditions in the low alignment condition, $\Delta M = -8.83, 95\% \text{ CI}$
 5055 $[-17.84, 0.18], t(69) = -1.95, p = .055$ compared to the high alignment condition,
 5056 $\Delta M = 2.37, 95\% \text{ CI} [-8.65, 13.40], t(69) = 0.43, p = .669$. Further, there was a

B. Chapter 4 appendix

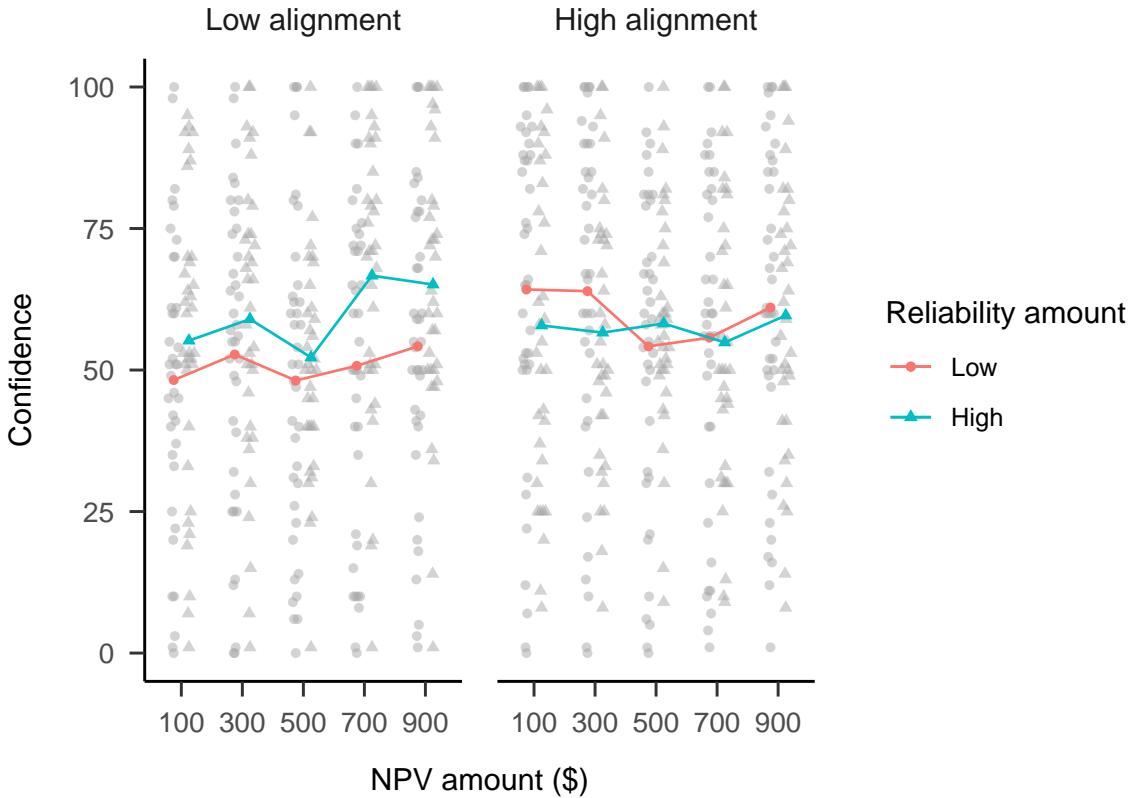

Figure B.41: Mean confidence. Error bars represent 95% confidence intervals based on the multivariate model. Note that this mixed factorial design does not allow for using confidence intervals to make inferences by “eye” across conditions.

5057 stronger linear trend of NPV amount in the low alignment condition, $\Delta M = 18.70$,
 5058 95% CI $[-0.87, 38.26]$, $t(69) = 2.44$, $p = .067$ compared to the high alignment
 5059 condition, $\Delta M = -6.40$, 95% CI $[-26.84, 14.04]$, $t(69) = -0.80$, $p = .891$.

5060 B.4.3 Discussion

5061 Experiment 4 found evidence for most of the hypotheses. As per Hypothesis 4.4,
 5062 laypeople responded appropriately to verbal reliability instructions in the high
 5063 alignment condition. Contrary to Hypothesis 4.5, however, participants also did
 5064 this in the low reliability condition. That is, regardless of the type of project display,
 5065 participants tended to use NPV more when they were told that it was reliable and
 5066 tended to use it less when they were told that it was unreliable. Further, there
 5067 was no evidence that this effect was moderated by alignment condition, contrary
 5068 to Hypothesis 4.3. However, the linear NPV amount trend was higher in the high

B. Chapter 4 appendix

5069 than low alignment condition, when averaging over reliability amount, as predicted
5070 in Hypothesis 4.2. This suggests that overall participants still make more use of
5071 NPV information when it is hard to compare between projects.

5072 Hypothesis B.4 was not supported, as there was no evidence of a main effect
5073 of alignment on participants' confidence in their allocation decisions. Instead,
5074 exploratory analyses showed that the difference in confidence between reliability
5075 conditions was greater in the low alignment condition. This may reflect participants'
5076 difficulty in making sense of their choices when alignment was low, given more
5077 confidence when assured of the reliability of NPV. In the high alignment condition,
5078 on the other hand, regardless of reliability condition, they had a way of using
5079 the reliability information. Further, confidence also seemed to increase more with
5080 NPV, on average, more when projects were dissimilar, which provides evidence
5081 for their reliance on NPV in this situation.

B.5 Experiment 5

5082 Experiment 5 further investigated the effects of alignment and explicit NPV
5083 Presence information on forecasting. The goal of this experiment was to replicate
5084 the forecasting results of Experiment 1, but with a sample that has investing
5085 experience. As before, the hypothesis was that people's forecasting would be less
5086 variable when comparing projects with alignable differences, than when comparing
5087 projects with non-alignable differences.
5088

B.5.1 Method

B.5.1.1 Participants

5091 Sixty people (2 female) were recruited from Reddit. Participants were compen-
5092 sated with a virtual Gold Award, which gives the recipient a week of a premium
5093 version of Reddit and 100 virtual coins. The average age was 28.17 ($SD = 8.73$,
5094 $min = 16$, $max = 61$). Table B.2 shows the between-subjects condition allocation.

B. Chapter 4 appendix

Table B.2: Experiment 5 group allocation.

Alignment	Reliability amount	N
High	Absent	19
High	Present	17
Low	Absent	14
Low	Present	10
Total	-	60

5095 B.5.1.2 Materials

5096 **B.5.1.2.1 Risky investment task** The only task that was used was the
5097 forecasting task used in Experiment 1, except that it was fixed by adding the
5098 relevant percentage intervals that were left out in Experiment 1, seen in Figure B.42.

5099 B.5.1.3 Procedure

5100 The procedure was the same as in Experiment 1, except participants only
5101 completed the forecasting task.

5102 B.5.2 Results

5103 B.5.2.1 Forecast mean

5104 A mixed factorial ANOVA was conducted to investigate the effects of align-
5105 ment and NPV presence on participants' forecasts. As seen in Figure B.43, the
5106 alignment \times reliability amount \times NPV amount interaction was not significant,
5107 $F(2.75, 154.16) = 0.72, p = .531, \hat{\eta}_p^2 = .013$. Despite this, as in the previous
5108 experiments, the interaction between the linear NPV trend and NPV presence was
5109 significant in the high alignment condition, $M = -0.12, 95\% \text{ CI } [-0.21, -0.02]$,
5110 $t(56) = -2.50, p = .015$, but not in the low alignment condition, $M = -0.05,$
5111 $95\% \text{ CI } [-0.16, 0.07], t(56) = -0.81, p = .424$.

5112 B.5.2.2 Forecast SD

5113 A mixed factorial ANOVA was conducted to investigate the effects of alignment
5114 and NPV presence on participants' forecast SDs. As seen in Figure B.44, there

B. Chapter 4 appendix

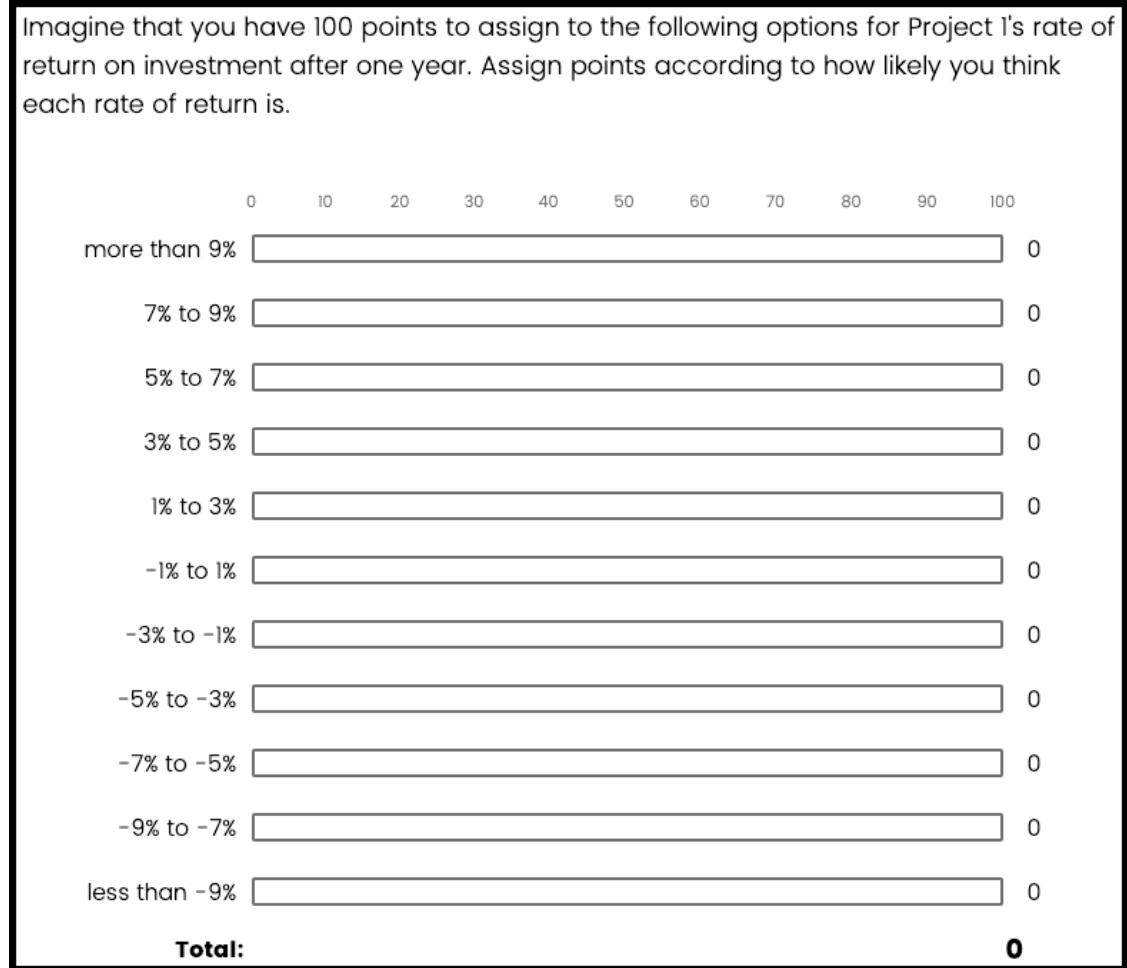

Figure B.42: An example of the forecasting task in Experiment 5. Border added for clarity.

were no significant differences between alignment conditions, $F(1, 56) = 0.41$,
 $p = .522$, $\hat{\eta}_p^2 = .007$. The alignment \times reliability amount \times NPV amount interaction
was not significant, $F(2.99, 167.18) = 1.27$, $p = .287$, $\hat{\eta}_p^2 = .022$. However, as
above, the interaction between the linear NPV trend and NPV presence was
significant in the high alignment condition, $M = 0.02$, 95% CI [0.00, 0.04], $t(56) =$
 2.06 , $p = .045$, but not in the low alignment condition, $M = 0.01$, 95% CI
[-0.02, 0.03], $t(56) = 0.38$, $p = .709$.

B.5.3 Discussion

Experiment 5 found that people with some investing experience responded to alignable information in the form of NPV when it is given, but did not show the

B. Chapter 4 appendix

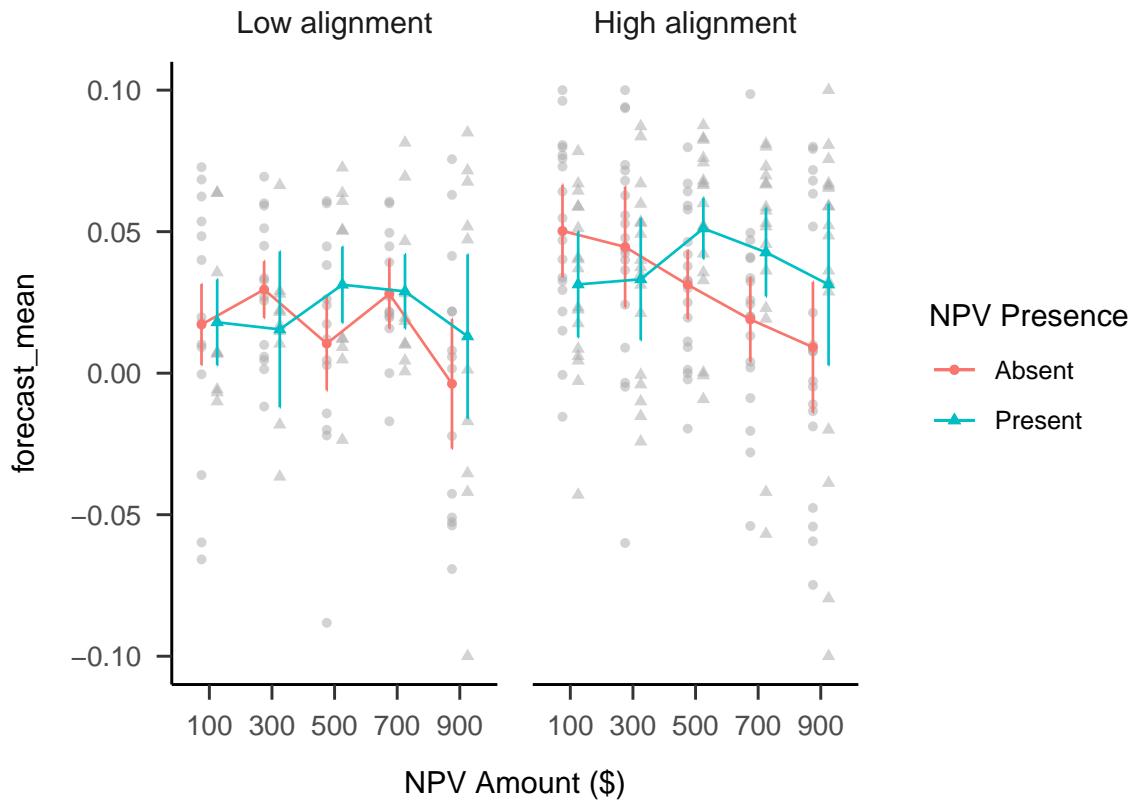

Figure B.43: Mean forecasts.

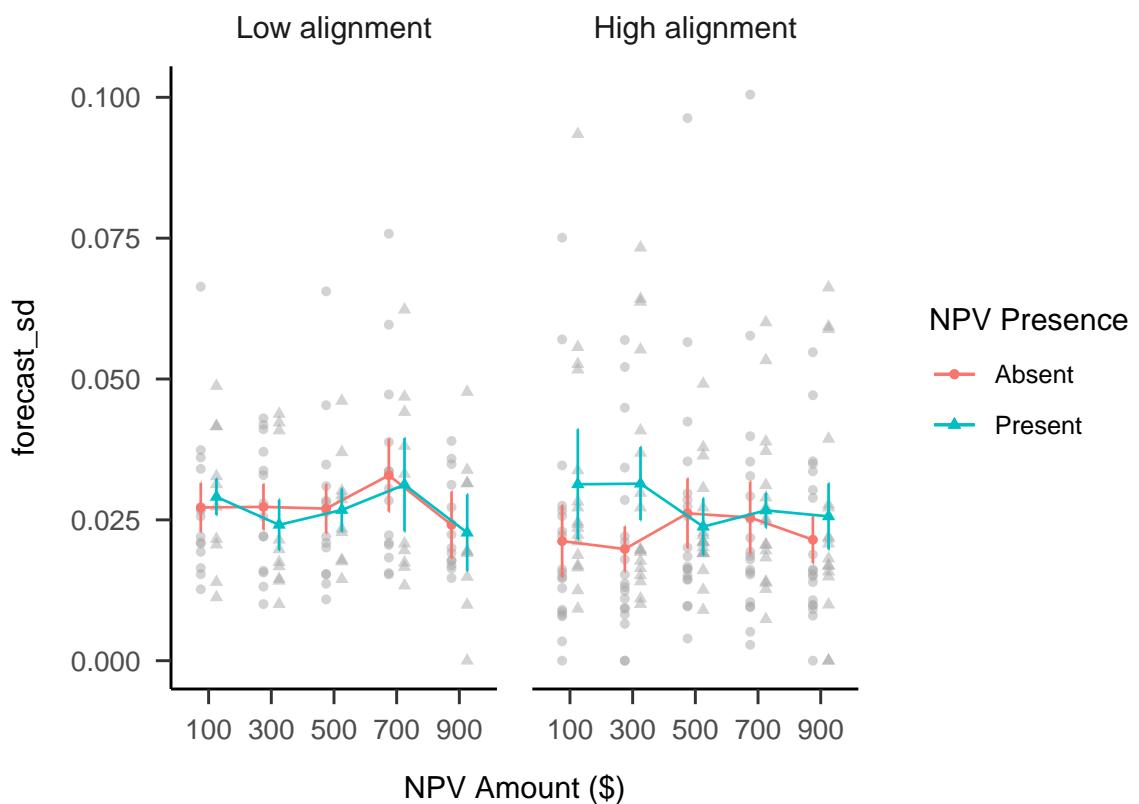

Figure B.44: Mean forecast SD.

Alignment	Reliability amount	N
High	Absent	97
High	Present	87
Low	Absent	101
Low	Present	104
Total	-	389

5125 same effect of alignment on forecast SD that was seen in Experiment 1.

5126 **B.6 Experiment 6**

5127 Experiment 6 further investigated the effects of alignment and NPV Presence
5128 information on forecasting. Experiment 5 did not clearly replicate the forecasting
5129 results of Experiment 1, potentially due to low power, so this experiment collected
5130 a much larger sample size. As before, it was hypothesised that people's forecasting
5131 would be less variable when comparing projects with alignable differences, than
5132 when comparing projects with non-alignable differences.

5133 **B.6.1 Method**

5134 **B.6.1.1 Participants**

5135 Three hundred and eighty-nine people (170 female) were recruited from the
5136 online recruitment platform Prolific. Participants were compensated at a rate
5137 of £5 an hour. The average age was 32.39 ($SD = 11.89$, $min = 18$, $max =$
5138 75). Table B.3 shows the condition allocation.

5139 **B.6.1.2 Materials**

5140 The materials were the same as in Experiment 5.

5141 **B.6.1.3 Procedure**

5142 The procedure was the same as in Experiment 5.

B. Chapter 4 appendix

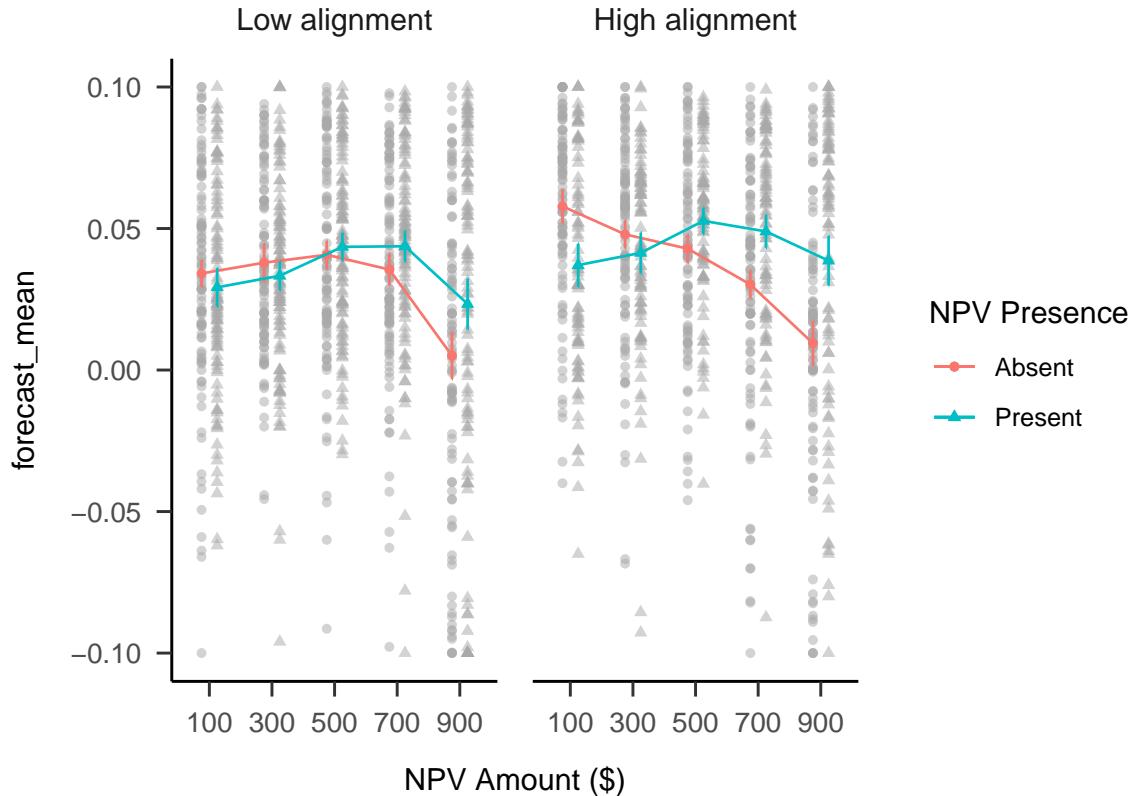

Figure B.45: Mean forecasts.

B.6.2 Results

B.6.2.1 Forecast mean

A mixed factorial ANOVA was conducted to investigate the effects of alignment and NPV presence on participants' forecasts. As seen in Figure B.45, the alignment \times reliability amount \times NPV amount interaction was significant, $F(3.08, 1, 186.45) = 3.13$, $p = .024$, $\hat{\eta}_p^2 = .008$. As in the previous experiments, the interaction between the linear NPV trend and NPV presence was significant in both the high alignment condition, $M = -0.13$, 95% CI $[-0.16, -0.09]$, $t(385) = -6.57$, $p < .001$, and in the low alignment condition, $M = -0.06$, 95% CI $[-0.09, -0.02]$, $t(385) = -3.28$, $p = .001$.

B.6.2.2 Forecast SD

A mixed factorial ANOVA was conducted to investigate the effects of alignment and NPV presence on participants' forecast SDs. As seen in Figure B.46, the

B. Chapter 4 appendix

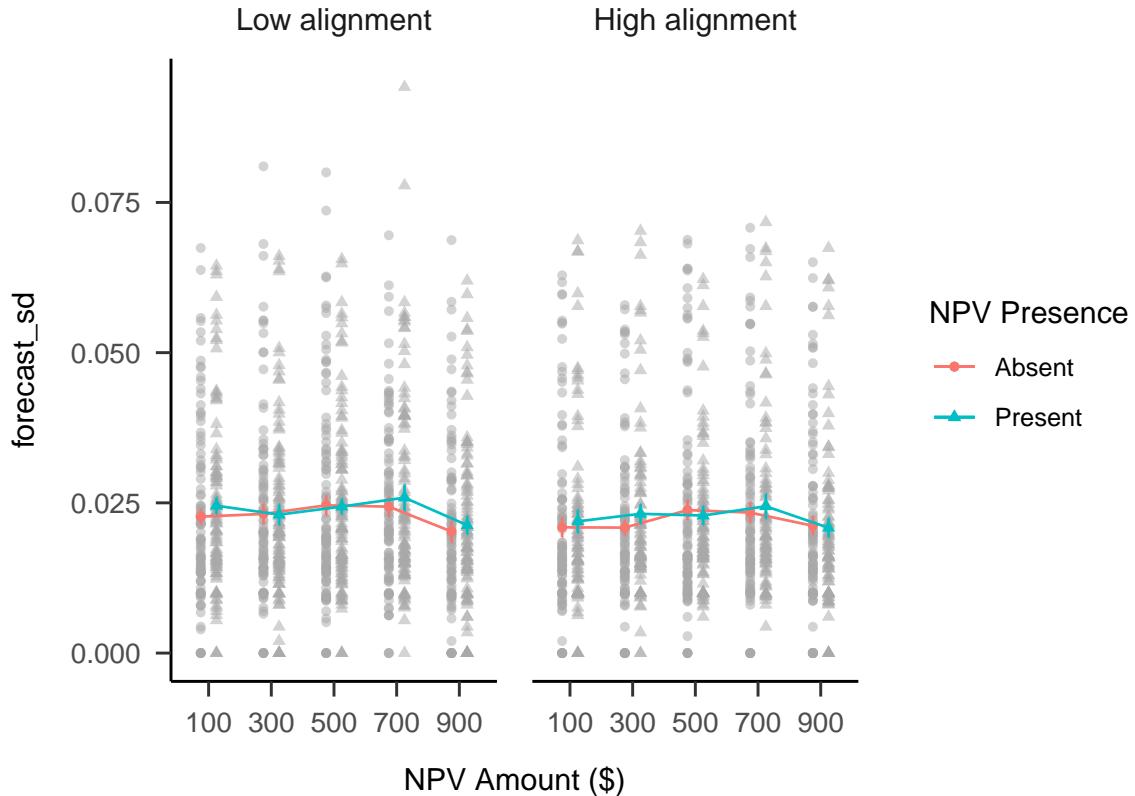

Figure B.46: Mean forecast SD.

alignment \times reliability amount \times NPV amount interaction was not significant, $F(3.45, 1, 328.06) = 0.82, p = .496, \hat{\eta}_p^2 = .002$. The main effect of alignment was not significant, $F(1, 385) = 0.64, p = .424, \hat{\eta}_p^2 = .002$.

B.6.3 Discussion

Experiment 6 did not replicate the effect of alignment on forecast SD seen in Experiment 1. However, participants still seemed to pay attention to the task, as seen in their higher forecasts for the high NPV project when NPV was present.

B.7 Experiment 7

Experiment 7 investigated potential ways to facilitate people's use of variance in capital allocation. Arguably, people's decisions should be moderated by variance, especially with a small set of projects. That is, when considering between two potential measures to use for capital allocation, underlying variance should serve as a

B. Chapter 4 appendix

Table B.4: Experiment 7 group allocation.

Hint	Variance	N
Hint salience	High	11
Hint salience	Low	11
No hint	High	9
No hint	Low	13
Salience only	High	19
Salience only	Low	16
Total	-	79

5168 moderator for decision making, with measures with narrow ranges being relied upon
5169 more than those with wider ranges. As such, this experiment presented participants
5170 with the same capital allocation scenario as in Experiment 2, but only in low
5171 numerical reliability displays. Experiment 7 varied both the variance associated with
5172 NPV, and the extent to which participants were explicitly hinted to use the variance
5173 information. It was predicted that participants would be more likely to moderate
5174 their allocations through variance when told explicitly to do so with increased
5175 salience for variance, than when only salience is increase, or when no hint is given.

5176 B.7.1 Method

5177 B.7.1.1 Participants

5178 Seventy-nine people (35 female) were recruited from the online recruitment
5179 platform Prolific. Participants were compensated at a rate of £5 an hour. The
5180 average age was 31.15 ($SD = 11.11$, $min = 16$, $max = 71$). Table B.4 shows the
5181 between-subjects condition allocation.

5182 B.7.1.2 Instructions

5183 As seen in Figure B.47, participants in the no hint condition saw the same
5184 instructions as in Experiment 1. As seen in Figure B.48, those in the salience
5185 only condition saw the instructions along with a sentence that drew attention to
5186 the *Cash inflow range* row. As seen in Figure B.49, those in the salience + hint

B. Chapter 4 appendix

Allocation task

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided.

In addition to those numbers, you will find each project's projected cash inflow for the first year (the money that it is expected to generate), and the net present value (NPV) that was calculated using those figures. It is usually unclear exactly what the future cash inflow is, so instead of a single cash inflow value, it will be given as a range (assume that all the values in that range are equally likely). Also assume that all the other elements that are required to calculate NPV (i.e., the discount rate and initial investment) are identical for all projects.

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest intrinsic quality.**

You will decide how to rank the projects in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Figure B.47: Instructions for the no hint condition. Border added for clarity.

5187 condition saw the instructions along with a specific description of how to use the
5188 variance information in their allocation decisions.

5189 **B.7.1.3 Project display**

5190 The project displays were the same as Experiment 2 (see Figure B.50).

5191 **B.7.1.4 Procedure**

5192 Participants read the instruction page as per their hint condition, and then
5193 proceeded to complete one set of ranking and allocations.

B. Chapter 4 appendix

Allocation task

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided.

In addition to those numbers, you will find each project's projected cash inflow for the first year (the money that it is expected to generate), and the net present value (NPV) that was calculated using those figures. It is usually unclear exactly what the future cash inflow is, so instead of a single cash inflow value, it will be given as a range (assume that all the values in that range are equally likely). Also assume that all the other elements that are required to calculate NPV (i.e., the discount rate and initial investment) are identical for all projects.

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest intrinsic quality.**

You will decide how to rank the projects in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Pay special attention to the cash inflow ranges as they are important to the decision making process.

Figure B.48: Instructions for the salience only condition. Border added for clarity.

5194 **B.7.2 Results**

5195 **B.7.2.1 Allocation**

5196 A mixed factorial ANOVA was conducted to investigate the effects of hint and
5197 NPV variance on participants' allocations. As seen in Figure B.51, none of the
5198 interactions or main effects were significant.

5199 **B.7.2.2 Ranking**

5200 A mixed factorial ANOVA was conducted to investigate the effects of hint
5201 and NPV variance on participants' project rankings. As seen in Figure B.52,

B. Chapter 4 appendix

Allocation task

You will be shown information about a number of projects that a consumer products firm is considering to invest in. Some specific information about the product itself is provided.

In addition to those numbers, you will find each project's projected cash inflow for the first year (the money that it is expected to generate), and the net present value (NPV) that was calculated using those figures. It is usually unclear exactly what the future cash inflow is, so instead of a single cash inflow value, it will be given as a range (assume that all the values in that range are equally likely). Also assume that all the other elements that are required to calculate NPV (i.e., the discount rate and initial investment) are identical for all projects.

We would like you to take the role of the manager in charge of capital allocation for the firm. This firm is specifically interested in investing in the development of high-end goods, so your valuations should reflect this. That is, even though there might be a market for the lower-end products in the descriptions that you will see, **you should be aiming to invest in the products with the highest intrinsic quality.**

You will decide how to rank the projects in order of investment priority, and decide how to allocate the capital available for investment this year among the different projects. Note that this is not the operational budget (advertising, etc.), but rather the funds to be used for investment in developing the new products. You will do this by selecting a percentage value for each project, such that the budget is allocated completely among each set of projects.

Pay special attention to the cash inflow ranges, because they imply the extent to which you should be relying on that particular NPV. NPVs with higher variance (greater cash inflow ranges) should be relied upon less. For instance, imagine two NPVs, one with a future cash flow range of \$100-\$1900 (range of $\pm 90\%$ around the average), and one with a range of \$900-\$1100 (range $\pm 10\%$ around the average). The average of each range is the same (\$1000), and yet the first estimate is more uncertain than the second. As such, with the first estimate, other factors should be used more in the decision making than the NPV, while with the second estimate, the NPV can be relied on more confidently. In general, ranges of less than 10% either way of the average are considered very low variance, and those more than 80% are considered very high variance.

Figure B.49: Instructions for the salience + hint condition. Border added for clarity.

only the main effect of NPV amount was significant, $F(2.03, 148.33) = 7.59$,
 $p = .001$, $\hat{\eta}_p^2 = .094$.

B.7.3 Discussion

Experiment 7 found that explicitly telling participants how to use variance information to moderate their allocations did not help them do so. However, there was an increased reliance on NPV with more hints in the ranking data. This suggests that the hint manipulations potentially simply increase participants' attention to NPV. It is possible that the study was under-powered, as there was substantial variance in both the allocation and ranking data. Future work should attempt to replicate this experiment with a larger sample.

5212 B.8 Experiment 8

5213 Experiment 8 tested the alignment and reliability effects found in the previous
5214 experiments, while addressing their limitations. Experiments 1 and 4 found a verbal
5215 reliability effect. That is, laypeople allocated more capital to a high NPV project,
5216 depending on how reliable they were told NPV was as a measure. Experiment 2
5217 found a lack of a numerical reliability effect. That is, business students allocated
5218 an equivalent amount of capital to projects associated with a high variance NPV,
5219 as projects with a low NPV. Testing these two effects in two different populations
5220 did not account for potential expertise effects. As such, Experiment 8 tested both
5221 effects with a naive sample. Further, Experiment 8 used projects whose features
5222 more clearly indicate their profitability, and included more project domains.

5223 B.8.1 Method

5224 B.8.1.1 Participants

5225 Fifty-two people (33 female) were recruited from both the online recruitment
5226 platform Prolific and a Psychology undergraduate sample at The University of
5227 Sydney. Participants from Prolific were compensated at a rate of £5 an hour, and
5228 participants from the undergraduate sample were compensated with course credit.
5229 The average age was 24.46 ($SD = 7.77$, $min = 18$, $max = 68$). Participants reported
5230 an average of 2.63 ($SD = 4.16$, $min = 0$, $max = 25$) years of work in a business
5231 setting, and an average of 0.81 ($SD = 1.39$, $min = 0$, $max = 5$) years of business
5232 education. The mean completion time was 35.57 ($SD = 71.96$, $min = 7.36$, max
5233 = 511.74) minutes. All conditions were presented within-subjects: alignment (low
5234 and high), NPV reliability type (numerical and verbal), NPV amount (low and
5235 high), and NPV reliability amount (low and high).

5236 B.8.1.2 Materials

5237 **B.8.1.2.1 Instructions** Participants saw instructions similar to the previ-
5238 ous experiments.

B. Chapter 4 appendix

5239 **B.8.1.2.2 Project display** Participants saw and responded to four webpage
5240 displays. At the top of each display was a text preamble, and underneath this
5241 a table that contained project descriptions. The two columns to the right of
5242 each description contained text boxes for participants to enter a value for the
5243 project ranking and budget allocation. Alignment was manipulated by asking
5244 participants to either compare between each of the project pairs (high alignment),
5245 or across all eight projects in the display (low alignment). For instance, in the
5246 high alignment display, participants had to compare between two railway projects,
5247 and then separately between two logistics projects, etc. However, in the low
5248 alignment display, participants had to compare railway projects to logistics projects
5249 directly. This was manipulated within-subjects, such that project descriptions
5250 were identical across alignment conditions and only the type of comparison (and
5251 the associated preamble text) varied.

5252 Figures B.53, B.54, B.55, B.56 show the four conditions that participants saw
5253 (counterbalanced). Each description provided the name of the business involved in
5254 the project, the type of project, three specific features of the project, an NPV, and
5255 an indication of reliability (either numerical through ranges or verbal through
5256 explicit labels).

5257 The value of each type of reliability was also manipulated. Explicit reliability
5258 was manipulated by varying whether participants were told that a project pair was
5259 in an industry in which NPV is considered a reliable or unreliable measure. Implicit
5260 reliability was manipulated by presenting NPVs alongside numerical ranges instead
5261 of verbal reliability information about them, and varying whether the range was
5262 high or low. Both of these were manipulated within-display, such that NPV was
5263 reliable for four projects in each display, and NPV was unreliable for the other four.

5264 Each project had an associated NPV, which was crossed with each project pair's
5265 intrinsic features. That is, each pair had one project with a high NPV and low
5266 intrinsic feature values, and one project with a low NPV and high intrinsic feature
5267 values. As such, a reliance on NPV was inferred if participants allocated the high

B. Chapter 4 appendix

For the following set of projects, the budget is shared among all eight projects.

The total budget is \$400 million.

Therefore, the sum of allocations for all the projects should be 400 and the rankings will be between 1 and 8.

<p>Business name: FreightCog. - Investment: <u>railway</u>. - Predicted project features: - Railway lines built: 5 a decade. - Number of seats filled by paying customers at peak hour: 2000. - Time before the train carriages will need to be serviced: 12 years. - NPV: \$128 million. (In this particular industry, NPV is a reliable predictor of project success.)</p>	Project ranking: <input type="text"/>	Budget allocation: \$ <input type="text"/>
<p>Business name: Railmont. - Investment: <u>railway</u>. - Predicted project features: - Railway lines built: 3 a decade. - Number of seats filled by paying customers at peak hour: 1200. - Time before the train carriages will need to be serviced: 7 years. - NPV: \$974 million. (In this particular industry, NPV is a reliable predictor of project success.)</p>	Project ranking: <input type="text"/>	Budget allocation: \$ <input type="text"/>
<p>Business name: Pharmacore. - Investment: <u>pharmaceutical</u>. - Predicted project features: - Pills pressed: 180000 an hour. - Shelf life: 12 months. - Probability of symptom reduction after a week: 54%. - NPV: \$952 million. (In this particular industry, NPV is an unreliable predictor of project success.)</p>	Project ranking: <input type="text"/>	Budget allocation: \$ <input type="text"/>
<p>Business name: Biotechly. - Investment: <u>pharmaceutical</u>. - Predicted project features: - Pills pressed: 300000 an hour. - Shelf life: 20 months. - Probability of symptom reduction after a week: 90%. - NPV: \$194 million. (In this particular industry, NPV is an unreliable predictor of project success.)</p>	Project ranking: <input type="text"/>	Budget allocation: \$ <input type="text"/>
<p>Business name: Pressbloom. - Investment: <u>national newspaper</u>. - Predicted project features: - Newspapers printed: 30000 a day. - Number of weekly advertisers: 48. - Ink that is not discarded due to impurities: 3000L a day</p>	Project ranking: <input type="text"/>	Budget allocation: \$ <input type="text"/>

<p>Business name: Solgistics. - Investment: <u>shipping logistics</u>. - Predicted project features: - Packages shipped: 480 a week. - Number of packages that do not spend time in a bottleneck: 240 a day. - Average accuracy of shipments: 57%.</p>	Project ranking: <input type="text"/>	Budget allocation: \$ <input type="text"/>

Figure B.56: Experiment 8 high alignment, numerical reliability display. Cropped for space (full display had eight projects).

B. Chapter 4 appendix

5268 NPV project more capital, or a reliance on the intrinsic features if participants
5269 allocated the low NPV project more capital.

5270 B.8.1.3 Procedure

5271 Participants viewed the instructions and then completed the ranking and
5272 allocation tasks in the four sets of project descriptions. The order of the display was
5273 counterbalanced, and the order of the project pairs on each page was randomised.

5274 B.8.2 Results

5275 A mixed factorial ANOVA was conducted to investigate the effects of alignment
5276 and NPV reliability type on participants project allocations. A direct comparison
5277 of the two alignment conditions was not possible due to the different allocation
5278 input scales, so the NPV reliability amount \times NPV amount interaction was tested
5279 separately in each alignment condition (see Figures B.57 and B.58). This interaction
5280 was significant for both the high alignment condition, $F(1, 51) = 27.81, p < .001$,
5281 $\hat{\eta}_p^2 = .353$; and the low alignment condition, $F(1, 51) = 7.63, p = .008, \hat{\eta}_p^2 =$
5282 .130. However, there was a significant effect of NPV in the low verbal reliability
5283 condition in high alignment, $\Delta M = 18.69, 95\% \text{ CI } [2.87, 34.52], t(113.10) =$
5284 3.17, $p = .012$; but not in low alignment, $\Delta M = 6.04, 95\% \text{ CI } [-9.24, 21.32]$,
5285 $t(121.35) = 1.06, p > .999$.

5286 B.8.3 Discussion

5287 Experiment 8 found that when variance was presented verbally, participants
5288 allocated according to the reliability information, for both low and high alignment
5289 conditions. When variance was presented numerically, there were no differences
5290 in allocations, for both low and high alignment conditions. Further, there was an
5291 effect of NPV in low reliability for the high alignment condition, but not the low
5292 alignment condition. This effect shows that people still relied on NPV more than
5293 they should when comparing across dissimilar projects.

B. Chapter 4 appendix

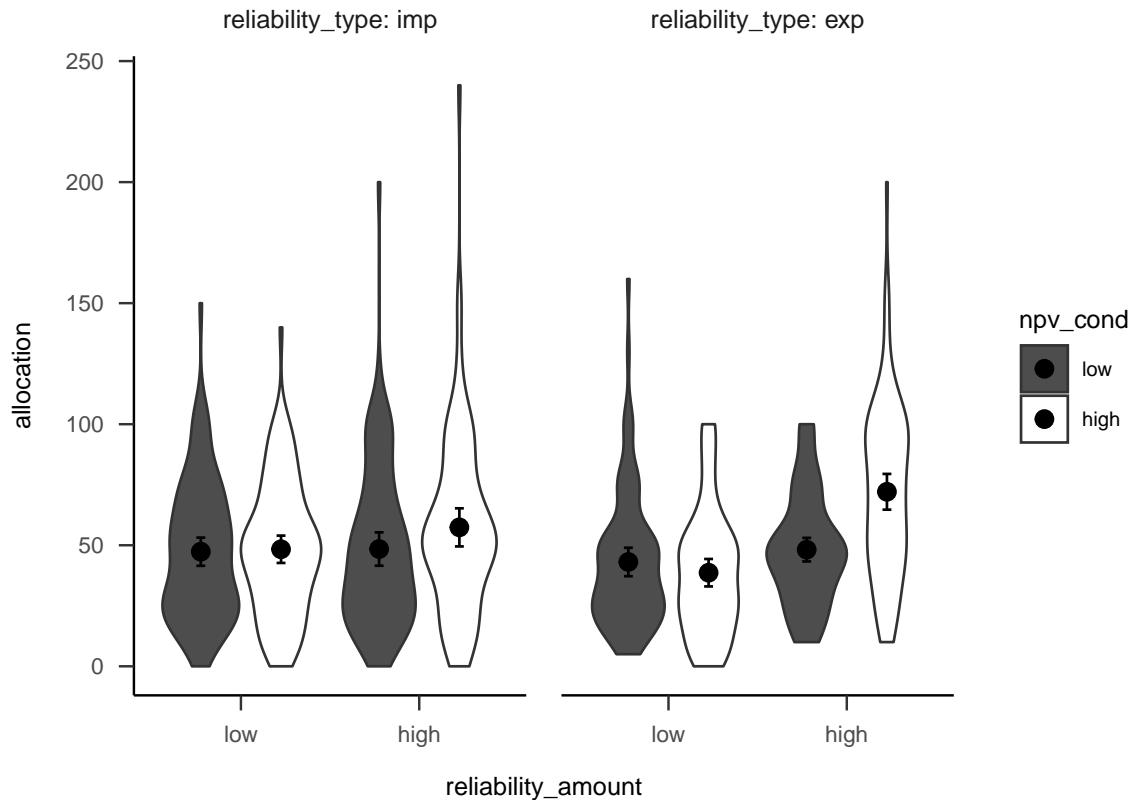

Figure B.57: Mean project allocation, for the low alignment condition. Error bars represent 95% confidence intervals.

5294 This experiment shows that similar to the previous experiments, when controlling
 5295 for presentation and domain, people still find it easier to allocate capital based
 5296 on explicit reliability information when projects are comparable. However, due
 5297 to the difference in scale across alignment conditions, a direct alignment effect
 5298 was more difficult to test than with the previous experiments. Further, similar to
 5299 Experiment 2, Experiment 8 showed that people without much business experience
 5300 also struggle to use range information in capital allocation to such an extreme
 5301 extent that they do not seem to be using any coherent allocation strategy.

5313

5314

5315 This appendix contains supplementary materials and analyses for the two
5316 experiments reported in Chapter 6.

5317

C.1 Experiment 1

5318

 Below are hypotheses that were tested, but were not sufficiently relevant for

5319

 Chapter 6 to be reported in the main text.

5320

Hypothesis C.1—Allocation similarity manipulation check for negative

5321

 anecdote. For negative anecdotes, allocations for the anecdote only low similarity

5322

 condition will be higher than those in the anecdote only high similarity condition.

C. Chapter 6 appendix

5323 **Hypothesis C.2—Relationship between allocation and perceived similarity**

5324 **for negative anecdote.** In the negative valence condition, the correlation between
5325 allocation and similarity rating will be negative

5326 **Hypothesis C.3—Relationship between allocation and specific-relevance**

5327 **for negative anecdote.** In the negative valence condition, there will be no
5328 correlation between allocation and specific-relevance rating in the low similarity
5329 condition, but a negative correlation in the high similarity condition.

5330 After the allocation task, participants were asked to rate the relevance of the
5331 anecdote to the target project. It was predicted that those that saw only an anecdote
5332 would be more influenced by the similarity of the anecdote than those that saw an
5333 anecdote as well as statistics. Therefore, the following hypotheses were tested:

5334 **Hypothesis C.4.** The similarity effect on specific relevance will be greater in the
5335 anecdote only condition than in the anecdote + statistics condition.

5336 **Hypothesis C.5.** The similarity effect on specific relevance will be greater in the
5337 statistics + anecdote condition than in the anecdote + enhanced statistics condition.

5338 Further, participants were asked to rate the relevance of the anecdote to other
5339 projects in the same industry. It was predicted that those that saw only an anecdote
5340 would be more influenced by the similarity of the anecdote than those that saw an
5341 anecdote as well as statistics. Therefore, the following hypotheses are tested:

5342 **Hypothesis C.6.** The similarity effect on general relevance will be greater in the
5343 anecdote only condition than in the anecdote + statistics condition.

5344 **Hypothesis C.7.** The similarity effect on general relevance will be greater in the
5345 statistics + anecdote condition than in the anecdote + enhanced statistics condition.

C. Chapter 6 appendix

5346 C.1.1 Method

5347 C.1.1.1 Participants

5348 **C.1.1.1.1 Power analysis** The sample size for Experiment 1 was determined
5349 by conducting power analyses using the `Superpower` package (Lakens & Caldwell,
5350 2019). The package uses experimental design, and predicted means and standard
5351 deviation, to conduct a priori power calculations. Data from Wainberg (2018),
5352 Jaramillo et al. (2019), and Hoeken and Hustinx (2009, Study 3) was used to
5353 determine realistic means and standard deviations for the evidence and similarity
5354 factors. According to the power functions, the resulting sample size is assumed
5355 to allow for an expected power of at least 80%.

5356 Data from Wainberg (2018) were used to determine the predicted means for the
5357 anecdote conditions. Specifically, the values for the high similarity condition were
5358 taken from the anecdote & statistics, anecdote & enhanced statistics, and statistics
5359 only conditions for the corresponding anecdote conditions. This was done because
5360 in Wainberg (2018) the anecdote was always of a similar case. Wainberg (2018)
5361 did not use an anecdote only condition, but Wainberg et al. (2013) did and found
5362 no significant differences between the anecdote only condition and the anecdote &
5363 statistics condition. As such, the same mean value was used for both conditions.

5364 It was hypothesised that there will only be an effect of similarity for the anecdote
5365 only and anecdote & statistics conditions. As such, the data from Hoeken and
5366 Hustinx (2009, Study 3) were used to determine the corresponding mean values for
5367 the low similarity condition. Specifically, each predicted mean was multiplied by
5368 the Cohen's d_z of the similarity effect in Hoeken and Hustinx (2009, Study 3).

5369 To determine the predicted standard deviation, the data from Jaramillo et al.
5370 (2019) Experiment 2 and Hoeken and Hustinx (2009, Study 3) were re-analysed to
5371 determine the coefficient of variation (CV) of each condition. Each CV was then
5372 converted to a standard deviation value in the relevant scale by multiplying the
5373 mean of the CV values by the predicted means from above.

C. Chapter 6 appendix

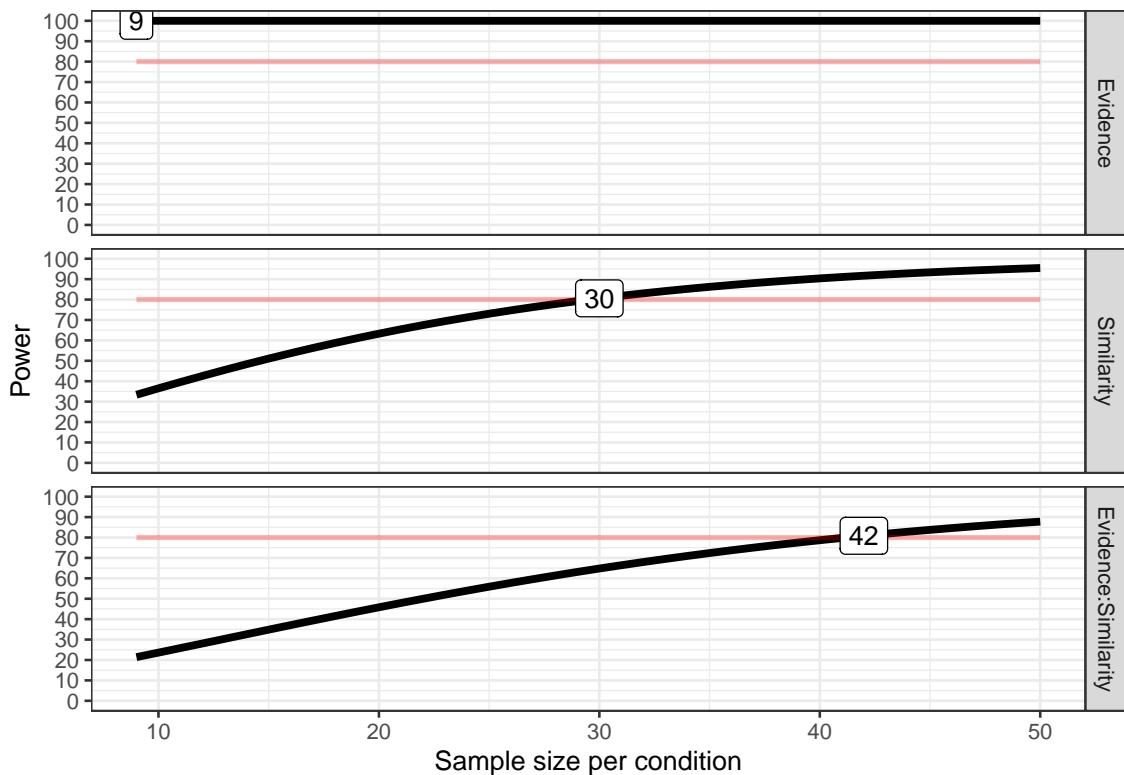

Figure C.1: Power curves for the similarity and anecdote effects.

Imagine you are a executive in a multi-business company and that you are presented with two projects to potentially invest in. Your job is to decide how to allocate the capital available in your budget between these two projects.

In a moment you will see a table that details the two target projects and relevant information about them.

Figure C.2: Experiment 1 general instructions. The two boxes were split between two separate web-pages.

5374 As seen in Figure C.1, the power analysis suggested that a minimum sample
 5375 size of 294 ($42 \cdot 7$) is required for the interaction effect with an expected power
 5376 of at least 80%.

5377 C.1.1.2 Method

5378 **C.1.1.2.1 Instructions** Figure C.2 shows the general instructions all participants received, and Figures C.3, C.4, C.5, and C.6 show the condition-specific instructions.

C. Chapter 6 appendix

Managers often find it useful to consult with previous case studies before making important decisions. As well as seeing the two target projects, you will also be provided with an example of a failed project with some information that was available just before the company decided to invest in it. Further, you are also provided with an analysis of this investment decision after it became clear that the project will not meet its expected return on investment.

Figure C.3: Experiment 1 specific instructions for those in the anecdotes only condition.

Managers often find it useful to consult with previous case studies before making important decisions. As well as seeing the two target projects, you will also be provided with an example of a failed project with some information that was available just before the company decided to invest in it. Further, you are also provided with an analysis of this investment decision after it became clear that the project will not meet its expected return on investment.

As a part of the relevant information that will be provided for each target project, you will be provided with measures of overall reliability and Net Present Value (NPV). The NPV is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. The higher the NPV, the better the expectations for each project. Both these measures were collected as part of a research study conducted by an international consulting company that aggregated data from thousands of other projects in relevant industries.

Note that the project in the case study was included in the research study, so its features are subsumed in the aggregated data.

Figure C.4: Experiment 1 specific instructions for those in the anecdote & statistics condition.

5381 **C.1.1.2.2 Allocation task** A horizontally integrated company is one which
5382 is made up of multiple businesses that operate in similar markets, and may have
5383 previously been competitors (Gaughan, 2012a). A vertically integrated company, on
5384 the other hand, is one which is made up of multiple business than operate in the same
5385 market, but in different levels of the supply chain (Gaughan, 2012b). A centralised
5386 organisational structure is one in which a company decisions tend to come from a
5387 specific business unit or leader, whereas a decentralised structure is one in which

C. Chapter 6 appendix

Managers often find it useful to consult with previous case studies before making important decisions. As well as seeing the two target projects, you will also be provided with an example of a failed project with some information that was available just before the company decided to invest in it. Further, you are also provided with an analysis of this investment decision after it became clear that the project will not meet its expected return on investment.

As a part of the relevant information that will be provided for each target project, you will be provided with measures of overall reliability and Net Present Value (NPV). The NPV is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. The higher the NPV, the better the expectations for each project. Both these measures were collected as part of a research study conducted by an international consulting company that aggregated data from thousands of other projects in relevant industries.

Note that the project in the case study was included in the research study, so its features are subsumed in the aggregated data.

Alongside its results, the research study also encouraged managers to use 'scientific thinking'.

Scientific thinking can be characterized as a process of objectively analyzing information about a given topic. A scientific thinker is one who very carefully considers the quality of each piece of information so as not to be unduly swayed by insignificant and/or less significant facts.

Progress in science is generally achieved via the deliberate process of obtaining quantifiable evidence through observation and/or experimentation. The scientific method requires that experimental and observational findings be reproducible and cautions against drawing strong conclusions from any single study or observation. You may recall from statistics that this scientific principle is consistent with the fact that small samples of observations tend to have a higher probability of error while larger samples tend to be more accurate. Scientific knowledge is therefore based on an accumulation of carefully designed studies or observations which lend support to a given assertion.

Figure C.5: Experiment 1 specific instructions for those in the anecdote & enhanced statistics condition.

C. Chapter 6 appendix

As a part of the relevant information that will be provided for each target project, you will be provided with measures of overall reliability and Net Present Value (NPV). The NPV is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. The higher the NPV, the better the expectations for each project. Both these measures were collected as part of a research study conducted by an international consulting company that aggregated data from thousands of other projects in relevant industries.

Figure C.6: Experiment 1 specific instructions for those in the statistics only condition.

5388 decisions can be made by separate units or people independently (Kenton, 2021).

5389 **C.1.1.2.3 Follow-up** Figure C.7 shows the follow-up questions.

5390 **C.1.2 Results**

5391 **C.1.2.1 Allocation**

5392 A two-way ANOVA was conducted to investigate the interaction of similarity (low
5393 and high) and anecdote conditions (anecdote only, statistics & anecdote, anecdote
5394 & enhanced statistics). The main text reports the more relevant interaction that
5395 excludes the enhanced statistics condition. There was a main effect of anecdote
5396 type, $F(2, 238) = 14.47, p < .001, \hat{\eta}_p^2 = .108$; and a main effect of similarity,
5397 $F(1, 238) = 38.91, p < .001, \hat{\eta}_p^2 = .141$. However, the interaction was not significant,
5398 $F(2, 238) = 2.16, p = .118, \hat{\eta}_p^2 = .018$. The difference between the anecdote only
5399 condition and the anecdote & enhanced statistics condition was not significant,
5400 $M = -9.24, 95\% \text{ CI } [-22.00, 3.51], t(238) = -1.43, p = .155$.

5401 **C.1.2.2 Manipulation check**

5402 Figure C.8 shows participants' ratings of the similarity of the anecdote to the
5403 target project. As intended, participants in the high similarity condition rated
5404 the anecdote as more similar to the target project than those in the low similarity
5405 condition, $F(1, 238) = 27.01, p < .001, \hat{\eta}_p^2 = .102$.

C. Chapter 6 appendix

Please answer the following:

Follow up

On a scale of 1 to 6, how similar do you think the Refinera project (the case study) is to the Enfuel project (the target oil project)? A choice of 1 indicates low similarity, and 6 indicates high similarity.

Justify your answer:

On a scale of 1 to 6, how relevant do you think the information about the Refinera project is for determining whether to invest in the Enfuel project? A choice of 1 indicates low relevance, and 6 indicates high relevance.

Justify your answer:

On a scale of 1 to 6, how relevant do you think the information about the Refinera project is for determining whether to invest in *any* oil well project? A choice of 1 indicates low relevance, and 6 indicates high relevance.

Justify your answer:

Figure C.7: Follow-up questions in Experiment 1.

5406 C.1.2.3 Follow-up

5407 Figure C.9 shows participants' ratings of the specific relevance question. There
5408 was no significant effect of evidence type $F(2, 238) = 0.96, p = .383, \hat{\eta}_p^2 = .008$; or
5409 similarity, $F(1, 238) = 1.54, p = .216, \hat{\eta}_p^2 = .006$. The interaction was also not sig-
5410 nificant, `r results_anecdotes_1$relevance_specific$anecdote_alignment`.

5411 Figure C.10 shows participants' ratings of the general relevance question. There
5412 was no main effect of similarity, $F(1, 238) = 3.32, p = .070, \hat{\eta}_p^2 = .014$, or interaction
5413 of similarity and evidence type, `r results_anecdotes_1$relevance_general$anecdote_alignmen`
5414 However, there was an unexpected main effect of evidence type, $F(2, 238) = 3.80,$

C. Chapter 6 appendix

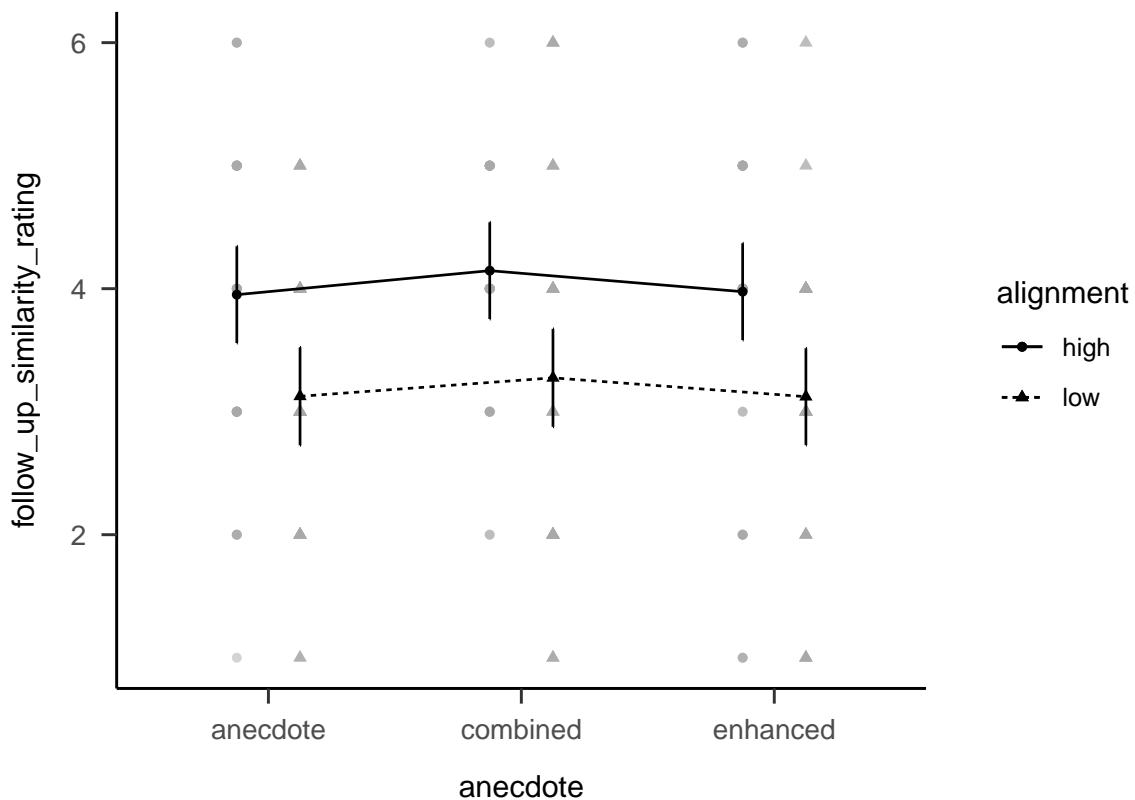

Figure C.8: Mean similarity rating of Project A (the target project) to the anecdote. Error bars represent 95% confidence intervals.

5415 $p = .024$, $\hat{\eta}_p^2 = .031$. A contrast analysis with Bonferroni correction revealed that
 5416 the anecdote only condition was rated significantly higher than the anecdote &
 5417 statistics condition, $\Delta M = 0.58$, 95% CI [0.06, 1.10], $t(238) = 2.71$, $p = .022$.
 5418 However, the difference between the two anecdote & statistics conditions was not
 5419 significant, $\Delta M = -0.39$, 95% CI [-0.90, 0.13], $t(238) = -1.81$, $p = .212$.

5420 Regression analyses were conducted to determine the relationship between
 5421 allocations and the follow-up ratings of similarity and relevance. As seen in
 5422 Figure C.11, similarity ratings were negatively correlated to allocations, $b = -3.53$,
 5423 95% CI [-5.70, -1.37], $t(242) = -3.21$, $p = .002$. Finally, as seen in Figure C.12
 5424 similarity ratings were positively correlated to specific relevance ratings, $b = 0.30$,
 5425 95% CI [0.17, 0.43], $t(242) = 4.59$, $p < .001$.

5426 Participants' justifications for the ratings were not analysed, so are not reported.

C. Chapter 6 appendix

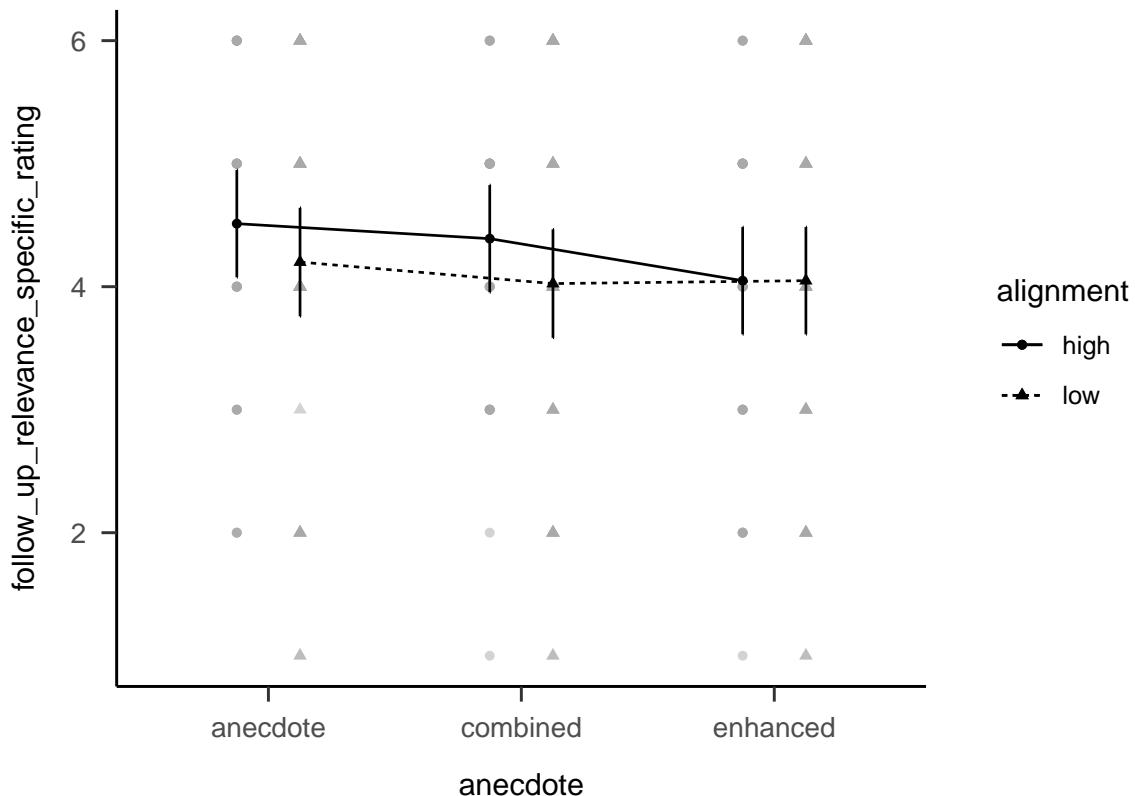

Figure C.9: Mean rating of how relevant participants thought the anecdote was to Project A (the target project). Error bars represent 95% confidence intervals.

5427 C.2 Experiment 2

5428 Figures C.13 and C.14 show the simulated data for the negative and positive
 5429 valence conditions, respectively.

5430 **Hypothesis C.8—Allocation similarity manipulation check for positive**
 5431 **anecdote.** For positive anecdotes, allocations for the anecdote only high similarity
 5432 condition will be higher than those in the anecdote only low similarity condition.

5433 The rating effects found in Experiment 1 were expected to replicate in the
 5434 Experiment 2 negative valence condition. The reverse effects were expected to
 5435 be found in the positive valence condition.

5436 **Hypothesis C.9—Relationship between allocation and perceived similarity**
 5437 **for positive anecdote.** In the positive valence condition, the correlation between
 5438 allocation and similarity rating will be positive

C. Chapter 6 appendix

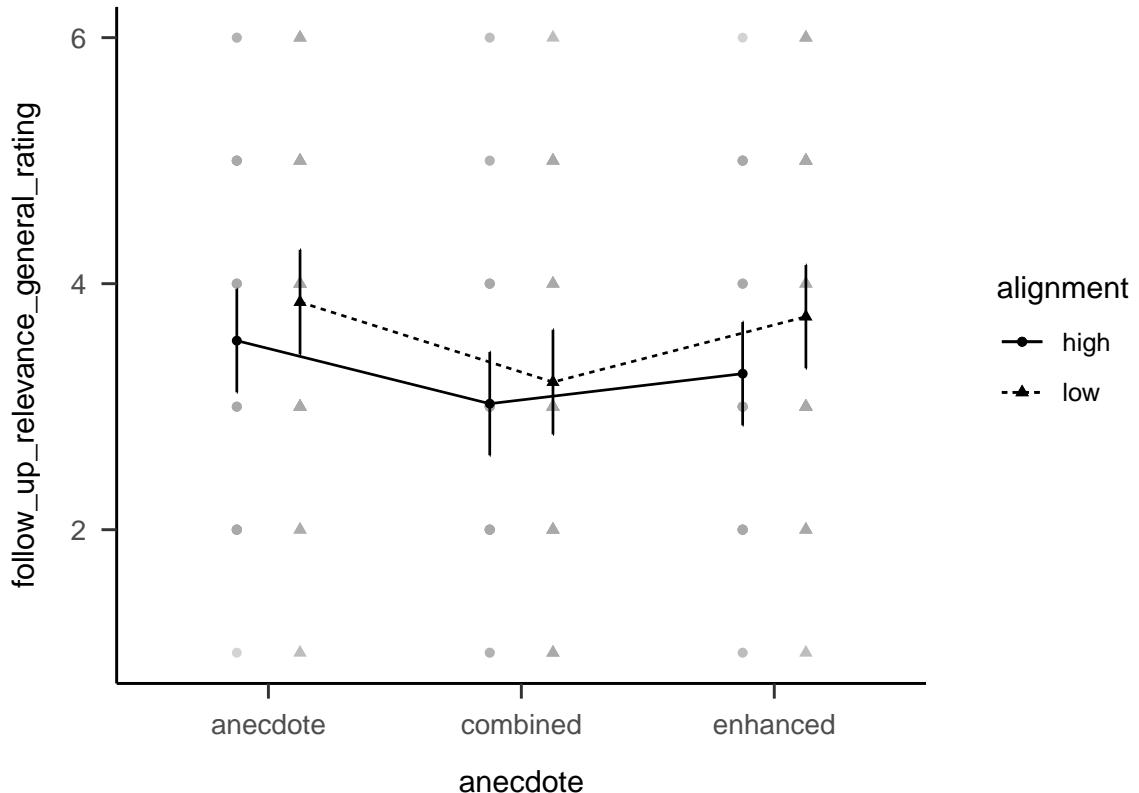

Figure C.10: Mean rating of how relevant participants thought the anecdote was to other oil projects. Error bars represent 95% confidence intervals.

5439 **Hypothesis C.10—Relationship between allocation and specific-relevance**
 5440 **for positive anecdote.** In the positive valence condition, there will be no correla-
 5441 tion between allocation and specific-relevance rating in the low similarity condition,
 5442 but a positive correlation in the high similarity condition.

5443 **Hypothesis C.11—Relationship between allocation and general-relevance**
 5444 **for positive anecdote.** There will be no significant correlations between allocation
 5445 and general-relevance rating

5446 C.2.1 Method

5447 C.2.1.1 Participants

5448 **C.2.1.1.1 Power analysis** A power analysis was conducted through simulation
 5449 of the effects implied by the hypotheses in Experiment 2. Data were simulated
 5450 with the same mean values as Experiment 1 for the effects that were previously
 5451 significant (i.e., similarity, statistics, and moderation effects), and no effect for the

C. Chapter 6 appendix

C. Chapter 6 appendix

5452 differences that were non-significant (as shown in Figures C.13 and C.14). The null
5453 effect was analysed using the two one-sided tests (TOST) procedure, or *equivalence*
5454 testing (Lakens et al., 2018), and setting the smallest effect size of interest to the
5455 smallest difference that leads to a significant equivalence between the combined low
5456 similarity and statistics only conditions in Experiment 1. Figure C.15 shows the
5457 results of this analysis, which suggested a total sample size of 96 (48×2).

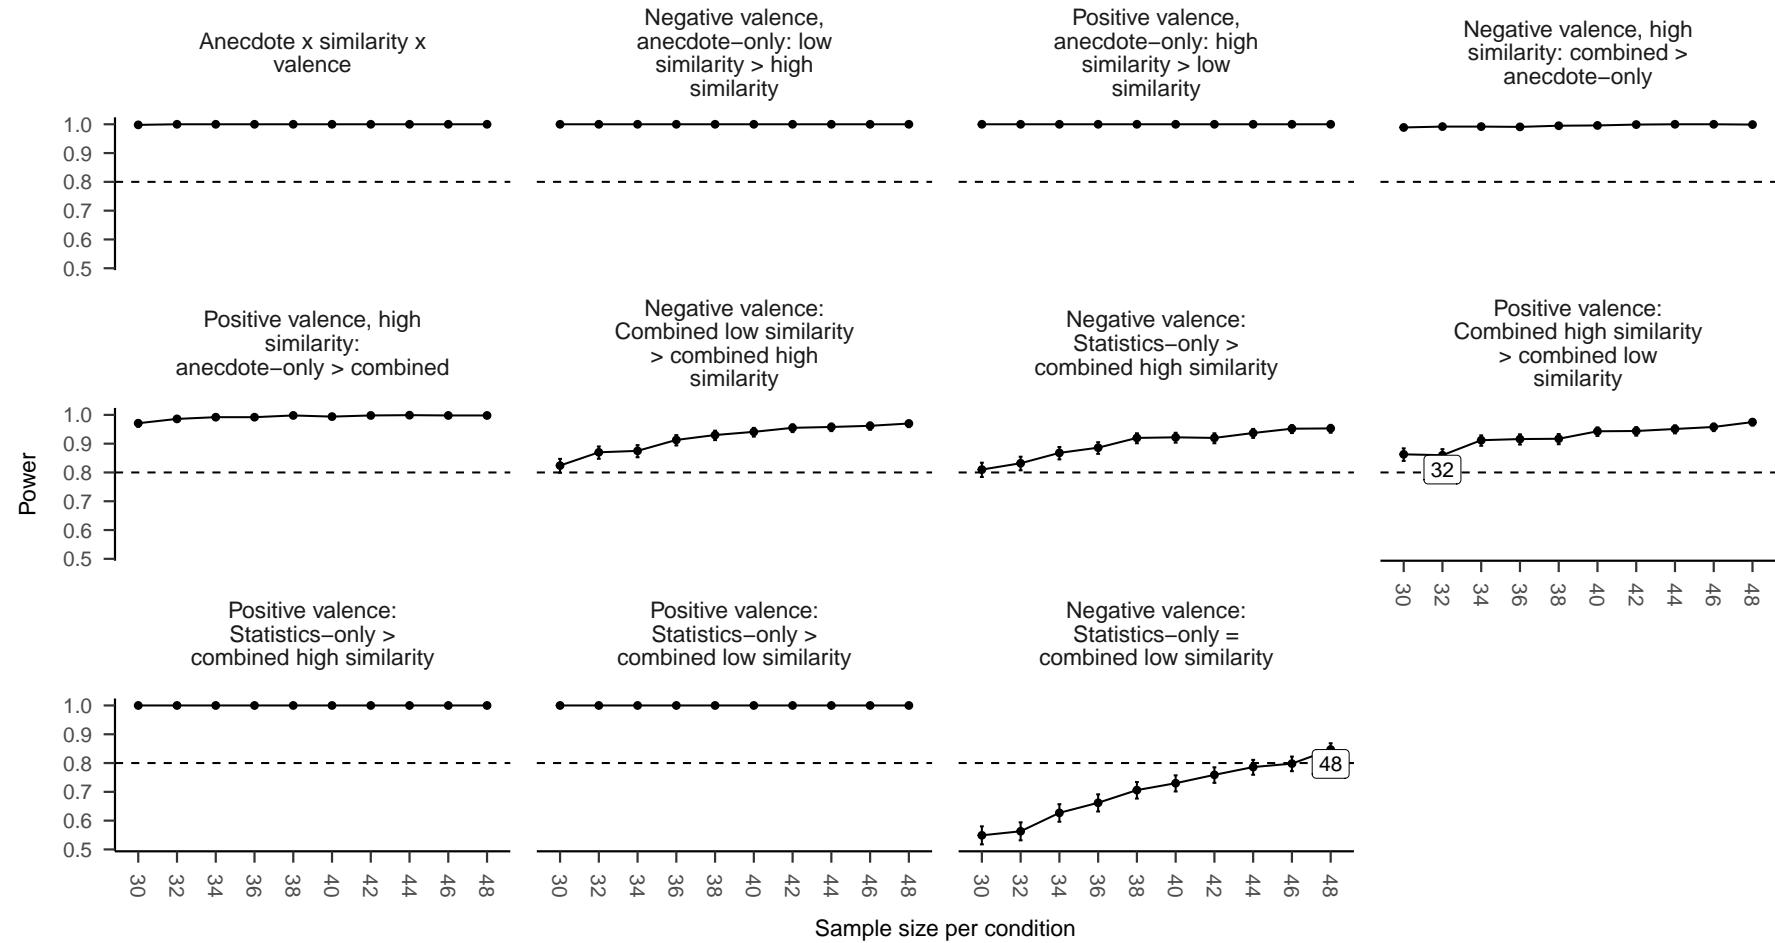

Figure C.15: Anecdotes Experiment 2 power curve. Labels indicate lowest sample size above 80% power.

C. Chapter 6 appendix

Instructions

Imagine you are an executive in a multi-business company and that you are presented with two projects to potentially invest in. Your job is to decide how to allocate the capital available in your budget between these two projects.

In total, you will see five of these project pairs (across five separate web pages). Each page will also contain relevant information about the projects.

Test yourself on the above instructions: How many pairs of projects will you see?

project pairs

Figure C.16: General instructions for Experiment 2.

5458 **C.2.1.2 Materials**

5459 **C.2.1.2.1 Instructions** Figure C.16 shows the general instructions all participants received, and Figures C.17, C.18, and C.19 show the condition-specific instructions.

5462 **C.2.1.2.2 Allocation task** The following were counterbalanced: 1. project variation (five latin square variations), which is the association of each display content with each within-subject condition; and 2. anecdote variation (two variations), which is the association of each project display and being either the target or comparison project. Table column order and project display order were randomised.

5467 **C.2.1.2.3 Follow-up questions** Figure C.20 shows an example of the follow-up questions.

5469 **C.2.1.2.4 Interstitial display** Figure C.21 shows an example of one of the interstitial displays.

C. Chapter 6 appendix

Instructions

Managers often find it useful to consult with previous case studies before making important decisions. As well as seeing the two target projects, you will also be provided with an example of a failed project with some information that was available just before the company decided to invest in it. This project was randomly chosen from a pool of thousands of projects. Others rated the similarity of all the case studies to the below target project based on dimensions such as the overall money invested, the quality of the proposal, the experience of the managers that proposed it, and the specific operations that were required. This case study was found to be, on average, as similar to the target as the others in the sample. Further, you are also provided with an analysis of this investment decision after it became clear that the project will not meet its expected return on investment.

Figure C.17: Experiment 2 specific instructions for those in the anecdotes only condition.

5471 C.2.2 Results

5472 C.2.2.1 Allocation

5473 **C.2.2.1.1 Similarity manipulation check** The similarity manipulation worked
5474 as expected, with the negative anecdote only low similarity condition being allocated
5475 significantly more than those in the high similarity condition, $\Delta M = 26.98$, 95%
5476 CI [18.12, 35.84], $t(186.55) = 6.01$, $p < .001$. For positive anecdotes, participants
5477 allocated more to the high similarity condition than those in the low similarity
5478 condition, $\Delta M = -22.62$, 95% CI [-31.48, -13.77], $t(186.55) = -5.04$, $p < .001$

5479 C.2.2.2 Ratings

5480 **C.2.2.2.1 Similarity manipulation check** Evidence for the similarity manip-
5481 ulation working was also seen in the rating data. Participants rated anecdotes in
5482 the high similarity condition as more similar to the target than those in the low
5483 similarity condition, $F(1, 94) = 48.36$, $p < .001$, $\hat{\eta}_p^2 = .340$.

5484 **C.2.2.2.2 Allocation is influenced by perceived similarity** As hypothe-
5485 sised, allocation was influenced by perceived similarity. That is, in the negative
5486 valence condition, there was a negative correlation between allocation and similarity

C. Chapter 6 appendix

Managers often find it useful to consult with previous case studies before making important decisions. As well as seeing the two target projects, you will also be provided with an example of a failed project with some information that was available just before the company decided to invest in it. This project was randomly chosen from a pool of thousands of projects. Others rated the similarity of all the case studies to the below target project based on dimensions such as the overall money invested, the quality of the proposal, the experience of the managers that proposed it, and the specific operations that were required. This case study was found to be, on average, as similar to the target as the others in the sample. Further, you are also provided with an analysis of this investment decision after it became clear that the project will not meet its expected return on investment.

As a part of the relevant information that will be provided for each target project, you will be provided with measures of overall reliability and Net Present Value (NPV). The NPV is the company's estimation of the future returns of the project. An NPV that is greater than 0 (zero) indicates that there is an expectation of profit. The higher the NPV, the better the expectations for each project. Both these measures were collected as part of a research study conducted by an international consulting company that aggregated data from thousands of other projects in relevant industries.

Note that the project in the case study was included in the research study, so its features are subsumed in the aggregated data.

Figure C.18: Experiment 2 specific instructions for those in the combined condition.
